DR. A. W. ADSON, Rochester: In addition to specific treatment, local surgical treatment, consisting of the removal of the sequestrum, or dead bone, is necessary. After the removal of the sequestrum, wet dressings saturated either in boric acid or salt solution should be applied, and if epidermization is slow, skin grafting may be resorted to later.

Value of the Study of Blood Pressure in Typhoid

DR. J. W. ANDREWS, Mankato: Blood pressure findings are of great value in typhoid. In this disease, without complications, there is always a marked hypotension, the systolic pressure ranging from 100 down to 75 or 80 mm. of mercury. The more severe the case, the lower will go the systolic pressure, probably the effect of the typhoid toxins on the splanchnic circulation. Frequent blood pressure readings will serve in this disease as a guide to prognosis. The leukocyte count is always valuable. There is always leukopenia.

Diagnosis of Cardiac Disease

DR. J. S. GILFILLAN, St. Paul: One should not place too much dependence on a systolic murmur in the diagnosis of a valvular lesion, but should demand other evidence. When a lesion is suspected, the confirming murmur should be sought for at different times and under various conditions.

Publication on Employment of Children.—The Children's Bureau of the U. S. Department of Labor has just issued in the Children's Year Series a pamphlet called "The States and Child Labor." The publications in this series do not go to the general mailing list, but are mailed on request to any address on that list. This new pamphlet summarizes briefly regulations placed by the various states on the employment of children in certain types of occupation. It presents an easy reference to material otherwise only laboriously obtained, and is of such wide interest that it was decided to bring it to the attention of the general list. The pamphlet may be had by both physicians and the laity by addressing the Children's Bureau, Department of Labor, Washington, D. C.

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below.

American Review of Tuberculosis, Baltimore

- Types of Tuberculous Lesions Found at Necropsy in a Military Hospital. E. D. Downing, Denver.—p. 631.

An Uncommon Case of Pleural Effusion.—In this case the effusion seems to have been "locked up" by adhesions. The diagnosis was in doubt. The patient complained of pain, which was a most distressing symptom up to the time when the fluid spread throughout the pleural cavity, and was completely and permanently relieved by that incident. Hence, the pain was probably due in large measure to the pressure of the accumulated fluid. Evidently, bands of tissue, resulting from a prolonged pleuritis, held the fluid within strict bounds.

Tuberculous Empyema.—Duboff's observations are based on a clinical study of twenty cases of tuberculous empyema.

Further Attempts to Reduce Resistance to Tuberculosis.—Using the macroscopic lesions of tuberculosis as an index of the acceleration of tuberculosis in the guinea-pig, Corper found that regional gland crushing, and the subcutaneous injection of virulent human tubercle bacilli in various sized doses, had no appreciable influence on the progress of the infection as compared with that obtained in control guinea-pigs. Lamp black injected subcutaneously, coincident with the tubercle bacilli, had a distinct retarding influence, while finely pulverized glass had a markedly accelerating influence, though not sufficient to be available for practical use in accelerating the guinea-pig diagnosis for the presence of tubercle bacilli in pathologic fluids.

Clinical Activity.—The object of this paper is to define clinical activity in such a manner that it may be of use in ordering the life and affairs of the tuberculous patient.

Etiologic Studies in Tuberculosis.—The danger of dust in rooms in a health resort, from telephone receivers, the danger of eating from utensils improperly cleansed, the danger from infected hands through handshaking or from knobs of doors, the danger of transmission by infected flies, at least in guinea-pigs, as a factor in causing tuberculosis has not yet been conclusively proved, and the experiments made by Brown et al. tend to belittle it. On the other hand, the danger of transmission of tubercle bacilli by kissing, or the transference of the tubercle bacilli to eating utensils, and thence, if not cleansed, to a second person, has been borne out. The authors express the hope that in publishing their experiments others may realize that the etiology of tuberculosis is not a closed book but one that contains many disconcerting and confused pages that need to be rewritten.

¹Cases of Urticaria Probably Due to Syphilis. Clinical Report. L. Hollander, Pittsburgh.—p. 55.
²Universal, Exfoliative Dermatitis from Sodium Cacodylate. W. A. Pusey, Chicago.—p. 57.

Ringworm Due to Trichophyton.—In Hartzell's first case, apart from the excoriations, the eruption, as a whole, bore considerable resemblance to a slowly spreading superficial nodular syphiloderm for which it might very readily have been mistaken on superficial examination. In addition to the affection of the skin, the nails of the index, middle and ring fingers of the right hand presented marked evidence of disease. They were rough and lusterless, with ragged and broken free borders. In scrapings taken from the skin and the nails an abundance of mycelium, presenting the morphologic characters of the trichophyton was readily demonstrated. In the second case a diagnosis of syphilis had been made by a former medical adviser, a genito-urinary specialist of considerable repute, and three or four injections of arsphenamin had been given, without any effect on the disease. In scrapings removed from the diseased areas Hartzell found numerous mycelia.

Papular Itching Eruption.—Withers reports four cases. In one case a complete microscopic study was made of a section removed from the axilla. The pathologic changes consisted of an acanthosis with hyperkeratosis, edema, perivascular infiltration and changes in the sweat glands, with keratocystomas of the sweat glands. The clinical picture consisted of a chronic circumscribed pruritus of the axillae and pubes principally, accompanied by a lichenification with keratocystomas of the deep sweat glands.

Extragenital Chancres.—Porter adds to the previous statistics on extragenital chancres the cases seen at the Barnard Free Skin and Cancer Hospital and the Washington University Dispensary. From August, 1905, to August, 1919, 225 patients presented themselves at the Barnard Hospital dispensary with a chancre as the chief complaint, or with the chancre still in evidence. Of these, fifty-five had extragenital primary sores, giving the rather high percentage of 24.5 per cent., or a percentage over half again as large as the highest percentage quoted by Montgomery. At the Washington University Dispensary there are recorded 106 cases of chancre, of which twelve were extragenital.

Arsphenamin Reactions.—Four cases are reported by Moore and Foley of severe reactions to the salvarsan or diarsenol brands of arsphenamin with an unusual blood picture, characterized by leukopenia, eosinophilia and increase in large lymphocytes and transitional groups, together with other evidence of destruction of the bone marrow. In a fatal case of salvarsan poisoning there was found at necropsy a markedly aplastic bone marrow showing degenerated cells and absence of the more mature forms of the myelocytic series. The fatal case showed for the first time, so far as can be determined, approximately the same kidney lesion as that produced in experimental animals by Pearce and Brown.

Urticaria Probably Due to Syphilis.—Hollander claims that no cases of puriginous lesions have as yet been attributed to syphilis. In his two cases the finding of syphilis was incidental as the patients consulted him on account of local, edematous, evanescent, papular, wheal-like, extremely itchy lesions, appearing and disappearing, which disappeared entirely under antisyphilitic medication.

Universal Exfoliative Dermatitis from Sodium Cacodylate.—Pusey's patient had psoriasis. He went to a sanatorium for treatment. He was given ten or twelve daily injections of sodium cacodylate, each three-quarters grain. A few days after the last injection a redness of the skin appeared, which quickly became universal and developed. When Pusey saw the man three weeks later he had a severe universal, dry, exfoliative dermatitis, quite similar in appearance to the Hebra type. The condition was absolutely universal. The skin was thickened, inelastic and red, and scaling profusely. On the hands and feet the process was particularly intense. There was extreme hyperkeratosis of the palms and soles, and the condition was only less pronounced on the backs of the hands and feet. There was a good deal of burning of

the general surface, and there were tenderness and discomfort on surfaces exposed to pressure. He had been confined to his bed for two weeks previously, during which time he had shown an afternoon temperature of from 101 to 102 F. Under treatment improvement was very slow.

 *History of Epidemic Encephalomyelitis. F. G. Crookshank, London.—p. 34.

History of Epidemic Encephalomyelitis.—Clinical occurrences of the nature that we now ascribe to encephalomyelitis, or encephalomyelomeningitis, Crookshank says have been recorded in modern times for at least 450 years. In great part, these occurrences have been noted as incidental to major prevalences, known historically as the sweating sicknesses, the epidemic catarrhs, or influenzas and the like. Special prevalences of these occurrences have also been described as manifestations of special diseases. These special prevalences have usually appeared shortly before or shortly after major "influenzal" epidemics, or else in geographical proximity to endemic-epidemic and endemic-influenza prevalences. Epidemic encephalomyelomeningitis represents an intensive and specialized reaction that has the same epidemiologic relation to pandemic influenza as have the prevalences and epidemics of "septic" pneumonia, of gastro-intestinal illness, and of other maladies described as occurring before and after the wide diffusions generally referred to as pandemic influenza.

*Attempts to Obtain a Transplantable Tumor in Higher Species of Animals. F. C. Mann, Rochester, Minn.—p. 331.
 *Chemical Composition of Blood in Cancer. R. C. Theis and W. S. Stone, New York.—p. 349.
 *Spirotera Carcinomata and Their Relation to True Malignant Tumors; Cancer Age. J. Fibiger, Copenhagen.—p. 367.

Transplantation of Tumors.—Experiments are reported by Mann in which attempts were made to transplant tumors of the dog and cat. Transplants of a mammary carcinoma of a dog were injected into 134 dogs, and transplants of a fibroma of a cat were injected into thirty-two cats. A transplantable tumor was not obtained in either series of experiments, although a few transplants grew for a short time. The transplants of the fibroma which were made in the donor grew. The results obtained in these experiments, in which tumor was employed, are strikingly similar to the results of autotransplantation, and homotransplantation of normal tissue. The problem of developing a transplantable tumor in the higher species of animals is, it would seem, closely allied to the problem of making homotransplants of normal tissue grow.

Chemical Composition of Blood in Cancer.—Theis and Stone determined sugar and the nonprotein nitrogen constituents, except creatinin and creatin, in blood obtained from 189 patients suffering from a malignant or allied disease such as leukemia or Hodgkin's disease. They found that nonprotein nitrogen and urea nitrogen are, in general, low in the blood of cancer patients. Amino-acid nitrogen is slightly above normal. Low results are not so obvious when other pathologic conditions coexist. Nonprotein nitrogen and urea nitrogen of blood are consistently low in clinically malignant cases. Uric acid, except in cases with

kidney complications and in two cases of melanoma, is not abnormal in cancer blood. Blood sugar is not generally increased in cancer. In 26 per cent of these cases (diabetics and nephritics excluded) the figure was somewhat above the normal and in 13 per cent. it was below normal.

Spiroptera Carcinomas.—Fibiger claims that by transmission of *Spiroptera neoplastica* (*Gongylonema neoplasticum*) to black and white rats and white mice, the development of neoplasms can be induced in the fundus of the stomach, and in rats in the tongue also. These neoplasms possess exactly the same histologic structure as malignant epitheliomas (keratinizing squamous cell carcinoma) in man and animals. They grow invasively into connective tissue and muscular tissue, and produce metastases in lymph nodes, perineural lymph spaces, the lung and the peritoneum. They continue their growth whether or not the spiropterae (as observed in the tongue) disappear entirely or only partly. They are transplantable, and when transplanted grow invasively into organs and tissues. Neither the metastases nor the transplanted tumors contain spiropterae, which have no share in their development and growth. That these tumors are true carcinomas cannot be doubted, and the fact that they may occur in younger animals is no reason why they should not be classed among the true malignant neoplasms.

- *Histamine and Pituitary Extract. J. J. Abel and D. I. Macht, Baltimore.—p. 279.

Benzylcarbinol.—Benzylcarbinol, or rose oil, an aromatic side-chain alcohol, Hjort and Eagan claim possesses local anesthetic properties which from laboratory studies seem to be superior to those of benzyl alcohol. The toxicity of rose oil, as determined on white mice and a dog, is about the same as that recorded by Macht for benzyl alcohol. Benzylcarbinol is more stable than benzyl alcohol, another point in favor of the former. The solubility of the rose oil is sufficient for its therapeutic use.

Anaphylactoid Phenomena from Thromboplastic Agents.—Hanzlik and his associates found that the thromboplastic agents rich in protein (thromboplastin and hemostatic serum) are distinctly harmful when injected intravenously and subcutaneously into guinea-pigs, producing anaphylactoid symptoms and injury to the circulation; and death with large doses of thromboplastin intravenously. Coagulen, which contains only traces of native protein, produced more pronounced anaphylactoid symptoms and also injured the circulation. The injurious effect of the thromboplastins and hemostatic serum the authors claim may be accounted for in part by trikresol (the preservative) and to a greater extent by the protein fraction. This does not appear to be true of coagulen which contains neither trikresol nor native protein. Caution is therefore necessary when employing these agents intravenously and subcutaneously. Kephalin appears to be relatively harmless as compared with the other thromboplastic agents studied.

Paradichlorobenzene and Paradibrombenzene.—The toxicity of paradichlorobenzene for earthworms, Sollmann says, suggests that it may be of value as an anthelmintic. Paradibrombenzene has similar chemical properties, but a somewhat different and less disagreeable odor, and would, therefore, be more suitable for internal administration. Both compounds have a high toxicity for earthworms. Experiments were tried on dogs but this method is inconclusive.

The substances deserve clinical trial when their toxicity has been more fully determined. So far, no toxic effects have been observed from oral administration, even of very large doses. Their absorption is probably very slight. In one experiment with paradibrombenzene, the absorption, judged by the bromine excretion, was only 3 mg. after the administration of 1 gm.

Experiments with Carvacrol.—Carvacrol is an isomer of thymol which can be produced at a low cost from spruce turpentine. It is said to be actively germicidal, and has been used as a counterirritant anesthetic against toothache. Sollmann says that from its composition, it seems probable that it might be used as an anthelmintic, especially against hookworm, in the place of the much more expensive thymol. The gastric administration of carvacrol to dogs, in doses up to 0.5 c.c. per kilogram (corresponding to about 30 c.c. per man) produced no toxic symptoms within three weeks. However, much smaller doses (0.1 c.c. per kilogram equivalent to 5 c.c. per man) apparently produced marked congestion of the small intestines, liver and kidneys. It is probably more irritant and toxic than thymol. This enjoins caution in its use. Sollmann is of the opinion that the drug seems to deserve clinical trial as an anthelmintic substitute for thymol. The administration, however, must be worked out cautiously. The routine should be the same as for thymol, and the dosage should be started considerably smaller, until the zone of safety has been determined.

Action of Chloramines.—Fantus and Smith studied the action of the chloramines on animal life. They found that unicellular animals are promptly killed by very dilute solutions of soluble chloramines. The chloramines are powerful irritants, causing inflammatory edema of the subcutaneous tissue, and even necrosis of the overlying skin on hypodermic injection, inflammation of mucous membranes on local application, and vomiting on oral administration. Chloramine-T depresses the central nervous system in the order of: brain, medulla, spinal cord. On intravenous injection, chloramine-T produces pulmonary edema, probably due to the chlorine in the molecule, as sodium p-toluene sulphonamine given intravenously does not produce such effect. The mechanism of the chloramine-T pulmonary edema is probably the same as that produced by chlorine gas inhalation described and studied by Schafer. The hemolytic power of chloramine-T is due chiefly to its alkalinity, as is shown by the fact that it is also displayed by chlorine-free sodium p-toluene sulphonamine. On the other hand, p-toluene sulphonamine, containing no dissociable alkali, is not hemolytic. Hemoglobin is changed to alkaline hematin by the first two bodies. Methemoglobin formation due to the chlorine in chloramine-T occurs; but merely to a slight degree, and was demonstrable only in the test tube. Dichloramine-T likewise is slowly hemolytic and slowly changes hemoglobin to methemoglobin in vitro.

Histamin and Pituitary Extract.—Cow says that if the uterus of the mouse is treated with histamine, it responds by relaxation, a response similar to that which the guinea-pig's uterus makes to epinephrin, while pituitary extract applied under the same conditions produces an increase in tonus. These results do not appear to bear out the hypothesis advanced by Abel that the plain-muscle-stimulating principles of histamine and pituitary extract are identical.

Histamin and Pituitary Extract.—Abel and Macht maintain that the uterus of the mouse and of the guinea-pig react in the same way toward pituitary extracts and salts of histamine, in the sense that both tracts of plain muscle respond to small and presumably comparable doses by contractions and increase of tonus, the uterus of the guinea-pig being the more sensitive of the two to minute doses of the two agents. Both tracts of plain muscle are easily paralyzed by comparable doses of pituitary extracts and of histamine salts. An interesting parallelism, therefore, is shown to exist in the manner in which comparably weak solutions of the two agents stimulate both tracts of plain muscle to an equal degree, while equally strong solutions of the two agents paralyze both tracts. The rat's uterus presents certain anomalies in its reaction to both pituitary extracts and histamine as compared with the reaction of the uterus of

the mouse or guinea-pig to these agents. The hypothesis that histamine may be present in the posterior lobe of the pituitary gland in two forms (a) as a histamine compound (b) as free histamine in equilibrium with the compound is now being put to the test by the authors.

*Case of Retroversion with Unusual Symptoms. L. F. Herz, New York.—p. 885.

Modern Medical Treatment of Chronic Ulcer of Stomach and Duodenum.—Weiss says that medical treatment, properly used, with the new and more exact methods we now have for diagnosis and observation, will cure more chronic ulcers than surgery. Not necessarily because it is better treatment, but because it is always used first.

Case of Retroversion with Unusual Symptoms.—Herz's patient complained chiefly of extreme weakness in the legs when standing on her feet for more than five minutes at a time. She would be compelled to sit down or lean against some object from sheer weakness. She also complained of dysmenorrhea, with passage of clots. The pain preceded the onset of menstruation by two days, and was often so severe as to confine her to bed. Both the weakness and dysmenorrhea were of five years' duration. Headache and backache were absent. Vaginal examination showed a third degree retroversion. A curettage was first done, and then a Gilliam suspension. The dysmenorrhea disappeared very promptly. The menses were somewhat profuse for a few times. The feeling of weakness in the legs disappeared more gradually, but as the patient regained her strength after the operation, she soon overcame this former disability.

Gastric Syphilis. Report of Case. H. D. McGanghey and J. I. Tyree, Joplin, Mo.—p. 21.

Adenoid Diphtheria.—In Myers' case the vault of the nasopharynx was filled with a yellowish white, thin membrane apparently covering an adenoid growth of immense proportions. Twelve hours after antitoxin examination, the post-nasal space was absolutely clear of any membrane. Myers directs attention to the fact that a case may clear up in its nasal aspect as far as the diphtheria is concerned and the adenoid growth might be the only seat of the infection. A low temperature (97.6 F.) with a rapid pulse (160) shows a toxemia. Taken in connection with the physical depression, plus the finding of a membrane in the nasopharynx it undoubtedly points to diphtheric infection of the adenoid tissue.

Blood Pressure in Yellow Fever. J. B. Guthrie, New Orleans.—p. 420.

Picric Acid as Disinfectant.—The use of 5 per cent. picric acid solution is advocated by Cassegrain as a preoperative disinfectant, because it thoroughly disinfects and can be used with soap and water; it does not irritate the skin, and it is approximately 40 per cent. cheaper than iodine.

Emetin in Complicated Cases of Influenza.—Points endorses the value of emetin hydrochlorid as a cure for the complicated cases of influenza.

Induction of Anesthesia and Analgesia.—Ficklin endorses the production of anesthesia by the oral administration of 5 c.c. of chloroform and 20 c.c. each of ether and liquid petrolatum. The maximum effects last from one-half to three-fourths of an hour. After an hour the patient rouses easily. Vomiting occurs in a small proportion of cases. Alarming symptoms have never been observed. The effects of the drugs are intensified and prolonged by the administration of morphin.

Local Anesthesia; Plea for Its More General Use. A. H. Noehren, Buffalo.—p. 1074.

Administration of Digitalis.—The points which Pardee emphasizes are: The initial dose must be sufficient to bring the patient to the stage of slight poisoning, which cannot be accomplished within a reasonable time unless we use doses larger than have been used ordinarily heretofore. If a continued digitalis effect is desired, it will not be obtained satisfactorily unless the patient is kept at a high level of saturation with the drug; his body must be nearly full, not nearly empty, or any failure to obtain good results cannot be interpreted as a failure of digitalis therapy. The nausea and vomiting which result from digitalis poisoning can be avoided if special case is used in observing the patient during the periods when he is receiving a daily dose which is above the average rate of 20 minims of the tincture a day at which the body can dispose of the drug. The variable susceptibility of different patients is an important thing to recognize. The amount of digitalis which will cause the appearance of these early signs of poisoning bears a definite relation to the weight of the patient. On the average a total dose of 2 minims of the tincture to each pound of body weight will produce these early toxic signs. If a patient, whose susceptibility is greater than the average, should receive such a dose, he would certainly be in danger of fibrillation of the ventricular muscle, and death. Those patients whose susceptibility for digitalis is less than the average must also be borne in mind. Therefore, if the average dose is insufficient to produce clinical improvement, and has not caused the appearance of toxic signs, continue to give the drug, watching carefully for the signs of early poisoning and not stopping digitalis until they appear. The average rate at which the body disposes of the drug, Pardee found to be 22 minims of the tincture a day, but here, again, there are considerable variations from one individual to another, as low a rate as 10 minims and as high as 40 minims daily being encountered. In spite of this the dose of 10 minims, twice a day, beginning three or four days after an initial digitalization, will not bring any patient to the toxic stage again very quickly, even though he may dispose of the drug at a much slower rate than the average.

Tubed Pedicle in Plastic Surgery.—The tubed pedicled skin flap was devised by Gillies. A strip of skin, usually between 2¼ and 3 inches in breadth, is raised from the neck to form the pedicle, its upper and lower extremities being left untouched. The two edges of the pedicle are accurately sutured together, skin edge to edge, by a continuous suture. The pedicle, now tubed, lies like a sausage between base and extremity. In the course of about three weeks, considerable arterial and venous anastomosis has occurred in the pedicle. The flap may now be raised from the chest and sutured into position on the face, the pedicle being left in its tubed condition. It is obvious that the pedicle cannot become infected. It will stand a considerable amount of twisting and even kinking, and the blood supply of the flap is enormously improved. When the flap has taken root on the face, the pedicle may be divided and returned to the neck, or, as is more commonly the case, the pedicle is divided at its neck

end, opened out until it remains flat, and spread on some other portion of the face. Once having placed the flap onto the face, it is possible to use the pedicle in a variety of ways and positions. Flaps of skin can thus be brought, by stages, from a long distance to the face. In other parts of the body which are the site of severe burns and contractions, larger flaps of skin may be used to relieve the disability by this method.

Feeding Solids to Nurslings.—The availability of solid foods to the nursing infant, a procedure commonly regarded as dangerous and unscientific, is discussed by Lowenburg. Of 128 patients, seventy-six, or more than one half, received solid food between the ages of six and eight months and thirty (about 25 per cent.) at the age of six months. None of these infants, except those suffering from severe diarrhea, received these prepared solids exclusively, i. e., milk in some form, either human or properly adapted cow's milk or both, was simultaneously fed. It is demonstrable, however, that the addition of these substances to the diet in early infancy is not only harmless but decidedly advantageous, and that less dependence need be placed on milk as an exclusive article of sustenance during this period of existence. In no case did vomiting occur as the direct result of beginning the administration of prepared solids. Diarrhea can be controlled absolutely and cured by the withdrawal of milk and milk foods and the substitution of properly prepared solids. Constipation is invariably relieved when the greater portion of the solid material fed is represented by green vegetables. The weight usually falls when milk is withdrawn entirely. The varieties of foods employed embraced all available and edible solids from either the vegetable or animal kingdom. Semisolids, such as cereals and soft eggs, were also included. No infant under 1 year of age was fed meat or fish. All varieties of cereals, eggs, potatoes, lima and string beans, spinach, peas, squash, carrots, beets, beet tops, swiss chard, boiled lettuce, stewed celery, baked apples, prune pulp, practically formed the group from which selection was made. Meats and fish have been used with good effect between the ages of 1 year and 18 months.

Transfusion of Citrated Blood; Technic and Indications. R. Lewisohn, New York.—p. 431.

Diagnostic Methods in Anemias.—This paper was abstracted in THE JOURNAL, May 31, 1919, p. 1638.

Treatment of Pernicious Anemia.—Hamman's article may be summarized as follows: Pernicious anemia is inevitably fatal and treatment at best can but promote and prolong the remissions that characterize the natural course of the disease. There is not conclusive evidence to prove that one method of treatment brings on remissions more constantly than another, nor that it more surely prolongs remissions thus begun. We depend solely on clinical impressions derived from the observation of individual patients for our estimate of the value of treatment. Such observation teaches us that spontaneous remission may be in every way as satisfactory as remission following the use of any method of treatment. In pernicious anemia as well as in all other conditions for which we have only symptomatic or palliative treatment, success depends more on a judicious selection from among all available methods of treatment and their proper combination than on a onesided advocacy of a single method. Rest, feeding, arsenic, transfusion, the eradication of foci of infection and, perhaps, also splenectomy have a definite place in the treatment of pernicious anemia. But who shall say which feature of the plan of treatment is the potent influence?

Congenital Heart Lesion with Unusual Origin of Pulmonary Artery.—In Plowden's case, leading from the right ventricle into the left ventricle, through the interventricular septum at its upper end, was an almost circular opening, one-half inch in diameter. No pulmonary artery could be found leading away from the heart. The only openings into or out of the right ventricle were the tricuspid orifice and the opening from the right to the left ventricles. The entire thoracic aorta was removed. Coming off from the middle of the under surface of the transverse arch of the aorta an abnormal branch was found. It measured one eighth inch in diameter. This vessel was also cut off very short and in view of the absence of the pulmonary artery elsewhere, Plowden believes that this must be the abnormally placed vessel.

Diagnosis and Treatment of Chronic Gastric Ulcer.—According to Moynihan, the results of the treatment of gastric ulcer by any system or by dietary or medicinal regimen, are vitiated by the lack of accuracy in the diagnosis of gastric ulcer. The most rational of all methods, in his opinion, is that introduced by Sippy, which appears to meet more combatantly those conditions in the stomach which must be controlled before an ulcer can have the chance to

heal. It is based on a recognition of the fact that the reduction of the acid in the stomach is the first necessity. This is attained by dilution of food, alkalization of the gastric contents every hour, and by the administration of fats. Chronic gastric ulcers undoubtedly heal under treatment or after the exercise of continued care in diet, but, Moynihan says, in the majority of cases they do not remain healed. Nevertheless, a really serious attempt to treat all cases of chronic gastric ulcer by medical treatment should be made. It is best to have no half measures. It is at least arguable that the necessity for surgical relief in many patients is due to a too perfunctory trial of medical treatment in the earlier attacks. The ideal would be to keep the patient under treatment until a roentgen-ray examination showed that the ulcer was healed. When a chronic gastric ulcer has refused to heal, or has recurred, after medical treatment, surgical treatment is necessary. Moynihan discussed the various operative processes resorted to, as a rule, and expresses his preference for partial gastrectomy over all other operations because it does away with any chance of recurrence of the ulcer, it results in a complete and immediate freedom from all gastric troubles, and it banishes the danger—it may be large or small, but it certainly is real—of a cancerous change taking place in the base of the chronic ulcer.

Hypochlorhydria and Air Swallowing.—Russell restricts the term "air" swallowing to those cases in which the air is swallowed only when food is taken. The amount swallowed varies in individual instances, and consequently the degree of discomfort varies. It sometimes leads to visible distention; it may lead to pronounced neurosis or neurasthenia; it may act reflexly on heart and vessels, leading to functional angina pectoris. It may not only be associated with, but apparently may even be caused by abnormal gastric secretion, either hyperchlorhydria or hypochlorhydria. It is difficult to treat, and when once acquired the habit is difficult to break.

Indolent Sores on the Fingers.—An indolent sore on the finger of a nurse, a dental surgeon, or a doctor is all too often the precursor of a systemic spirochetal infection, and, as time is a factor of paramount importance, McKenna emphasizes the necessity of having serum from such a sore examined early, and, if need be, often, for the micro-organism of syphilis. He cites three cases in point.

 *Dextrocardia, Complete and Incomplete. B. Parsons-Smith.—p. 1076.

Artificial Stimulation of Muscles.—Excluding the muscular dystrophies and injury due to trauma and toxins, Cooper believes that all muscular atrophy is of the disuse type—that is, it is caused by suspension of the normal function of contraction and relaxation. The condition and tone of a muscle are largely dependent on their function—interchange between the cell and surrounding lymph taking place during contraction and relaxation. Prevention of atrophy and restoration of atrophied muscles by rhythmic contractions is, therefore, a reasonable line of treatment. Artificial stimulation of muscle conserves the nervous energy of the patient, and in most cases of injury is the only method that can be employed. Of methods of artificial stimulation, electrical is the most valuable. Treatment by electrical stimulation is governed by the consideration of two factors: (1) The degree of contraction produced, and (2) the degree of pain caused by the stimulation. Pain is largely a matter of the length of waves employed and the uniformity of the interruptions. Apparatus devised to give a uniform type of interruption yields the best results. Fatigue is a toxic phenomenon due to accumulation of lactic acid. There is no risk of fatigue if a proper blood supply is ensured and a short interval allowed

between the contractions. Practical experience has demonstrated the value of artificial stimulation in restoring the condition of wasted muscles and in preventing atrophy.

Dextrocardia.—Smith reports four cases. In two cases the transposition not only affected the heart but also the liver and the stomach; in the other two cases the heart was transposed, but the liver and stomach occupied their normal positions. Smith points out that associated with complete transposition of viscera, dextrocardia does not incapacitate and is usually diagnosed by accident. Dextrocardia without transposition of viscera is of serious moment. Symptoms of incompetence are bound to appear sooner or later; these latter include dyspnea, palpitation, insomnia, faintness, pain, etc., and result from a general visceral overcrowding, the liver impeding the movements of the heart and the upper lobes of the right lung. Patients with dextrocardia without transposition invariably lay stress on the pains they experience both during effort and when resting; these pains, depending on the visceral overcrowding, are both local and referred local, when they denote pressure on the intercostal nerve or brachial plexus, referred when the vagus or its intracardiac endings suffer inordinate stimulation. Dextrocardia without transposition is usually if not always, complicated by actual malformation of the heart and great vessels. In one of Smith's cases it was considered that the ventricular septum was perforate. Likewise other congenital derangements may be present, pulmonary stenosis or atresia, transposition of great vessels, incomplete septums, patent ductus arteriosus, etc.

Deficiency Diseases. J. Comby.—p. 659.

Vaccine and Serotherapy of Epidemic Meningitis.—Lewkowicz presents what seems to be conclusive clinical evidence that the lateral ventricles are the principal and essential seat of the infectious process, and that the meningococci

spread from this hotbed through the entire subarachnoid space. The antiserum therefore, he declares, should be injected into the lateral ventricles from the very first and be reinjected daily, on alternate sides, or simultaneously on both sides every third day. The amount of the antiserum should be from 10 to 20 c.c. He urges the use of vaccine at the same time, from the very start. This tends to induce a general immunization which is a potent aid in the cure. He punctures the skull with a Götze grooved drill, 1.5 mm. wide, in a hand-drill. The needle is 1 mm. in diameter and 7 or 7.5 cm. long. A brass guide for the needle is introduced through the groove in the drill before the latter is drawn out. The brass guide inside the needle prevents obstruction with tissue. The tip of the needle is not sharp, as the only obstacle it has to force is the dura. The puncture is made anywhere along the top of the skull, 3, 4 or 5 cm. from the median line, pointing the tip of the needle toward the center of the skull. The depth of the puncture should be about 40 mm. for infants; 50 to 60 mm. for older children, and 60 to 75 mm. for adults. The fluid should not be injected until the needle is certainly in the ventricle. This is proved by the cerebrospinal fluid flowing from the needle and by the drop in tension as the antiserum spreads in the ventricles. It is important, therefore to have a manometer with three-way stopcock interposed between the needle and the syringe. The tension should not surpass 60 to 80 mm. mercury for older children and adults, and 40 or 50 for infants.

After the injection he leaves the needle in place for ten minutes to let the tension fall. Then he draws the needle half way out and leaves it for fifteen or thirty minutes, by which time the puncture canal has been plugged with a clot and there is no further oozing. In renewing the injections he trephines always at a point 1 or 1.5 cm. at least beyond the last points. His mortality was 36 per cent. in his last series of twenty-two cases, but analysis shows that a defective antiserum or a fulminating course from the start explained all the fatalities. In one instructive case the antiserum displayed a notably favorable action up to the twelfth day. Then the following injections, the sixteenth and seventeenth days, induced anaphylactic phenomena. Hence he warns not to give horse antiserum for longer than the thirteenth day, relying on the vaccine used from the start to carry on the work. In some mild cases the vaccine alone proved effectual, the blood serum showing an antibody content equal to that of the commercial antisera. He explains how there is a constant current from the ventricles to the surface of the brain and of the spinal cord, the ventricles being the secreting area and the subarachnoid space the resorbing area. He has been applying this primary ventricle serotherapy since 1914, and has a total record of eighty-four cases.

Bronchiectasia in Children.—D'Espine has encountered three cases of bronchiectasia among the 4,916 children that have passed through the children's clinic at Lausanne in over nine years. One girl of 8 had a large area of dulness at the left base with signs of a cavity and bronchitis, and incurred finger-nails. She improved under treatment and a year later auscultation gave normal findings but the nails showed no change. The same deformity of the nails plus drumstick fingers was noted in one of the two other cases with necropsy.

Complete Masculine Pseudohermaphrodite.—Schwartz operated on a young widow for bilateral inguinal hernia. Her external genital organs were absolutely normal but the hernias proved to be testicles. He was careful to leave one of the testicles in place in this androgynoid.

Gastric Ulcer.—Pron reports the findings years after pylorotomy for an old gastric ulcer. They show that the ulcer was the consequence and not the cause of the hypersecretion as the latter persisted unmodified after the ulcer region had been resected. The case teaches further the necessity for dietetic and medical measures being kept up for some time after operative treatment for old rebellious ulcers.

Instrumental Orthopedics.—Bidou gives an illustrated description of a device to be fastened to a crutch by which the hand moving a small lever controls an invisible wire passing over the shoulder and fastened to the knee or shoe, and thus lifts and lowers the paralyzed limb. With two of these crutches the paraplegic can soon learn to get about easily. Bidou emphasizes that the principles of this instrumental orthopedics can be applied to any motor impotency by studying and utilizing the motor capacity left in remote regions.

*Standard Weight Curve of Infants. A. Lesage.—p. 351.

*The Wassermann Reaction in Children. F. Saint Girons.—p. 353.

Buttermilk and Skimmed Milk in Infant Feeding.—Marfan regards buttermilk as very useful in the transition from nothing but water to the ordinary food, for bottle babies under 5 months old with ordinary or choleric diarrhea. It should never be given exclusively for more than two weeks, he says, nor in case of constipation, nor during the acute phase of the diarrhea, as water alone is called for during this stage; and buttermilk should never be given when there is fever. Several have reported cases of scurvy from prolonged buttermilk feeding. The buttermilk is made fresh, daily, in his service; the proportion of lactic acid is not over 5 gm. per liter. It cannot be sterilized alone, so it is made into a thin gruel with about 12 gm. of rice flour and 30 gm. saccharose to the liter, and the whole is cooked gently for twenty or twenty-five minutes, whipping it constantly with a cream whip. Cooked in this way it keeps well when distributed in bottles and heated to 115 or 120 C. But this sterilization is not required if the buttermilk is consumed within twenty-four hours, as in his service. When buttermilk is not available, condensed skimmed milk may be borne better than skimmed ordinary milk. Various substitutes more digestible than the butter in milk have been suggested, lipanin, cod liver oil, lard, olive oil, and coco oil, but these attempts are still tentative as yet.

Standard Weight Curve for Infants.—Lesage has computed the average from the standard weight curves published by Budin, Marfan and others. From this he has computed a standard normal range, adding 500 gm. to the average figure for the upper extreme, and subtracting 250 gm. for the lower. This range represents the normal, and the mothers are not frightened as is usual when the standard weight is given as a single figure. His own single figure average runs from 3,800 at the first month to 8,500 at the tenth.

The Wassermann Reaction in Young Children.—Saint Girons reiterates that a negative Wassermann reaction does not exclude syphilis in infants and children, and a positive reaction in children is not in itself alone a positive sign of syphilis. Even with positive reports from different laboratories, syphilis should be suspected, but in the absence of any other signs this cannot be accepted as positive proof.

*Hemophilia. P. Nobécourt.—p. 452.

*Familial and Hereditary Exophthalmic Goiter. P. Harvier.—p. 457.

Recent Progress in Pediatrics.—Lereboullet and Schreiber mention as important progress since the beginning of the war the founding of the chair of hygiene for young infants and of the puericulture school, both at the Paris medical school. They review recent publications all of which have been summarized in these columns, and refer to some society reports, including Lesné's case of septicemic sporotrichosis involving the brain in a boy of 4. Also Nobécourt's three cases of pneumococcus pleurisy in infants successfully treated with pneumococcus antiserum. Some commend and others denounce lavage of the pleura after pleurotomy; it is done by the Dakin technic. Spirometer exercises are recommended for children to shorten convalescence from purulent pleurisy. This latter, Comby affirms, is like a "hot abscess." The success of a single injection of an autovaccine in a 7 months infant with a diffuse suppurating skin disease was reported by de Pfeffel, but another infant showed only improvement, and finally severe glandular involvement and exacerbation of the preexisting eczema proved fatal. Five injections of the vaccine had been given in this case.

Rousing of Inherited Syphilis by Intercurrent Infection.—Hutinel and Nadal discuss the puzzling clinical pictures presented when measles, pneumonia, nephritis or other infectious disease is distorted by an underlying, possibly hitherto latent and unsuspected inherited syphilis. Some instructive cases are reported, including one in which during measles at 4, the inherited syphilis flared up in the form of cerebral hemiplegia. In another case a mild nephritis started a train of cerebral symptoms with coma for twelve hours. Simple infectious sore throat in another case roused an encephalitis with meningeal reaction, and in one young infant, recovering from cerebrospinal meningitis, hydrocephalus developed. In all these and in others after typhoid, prompt specific treatment tended to eliminate the puzzling element of the inherited syphilis affecting the various organs and especially the brain and meninges. Chorea in particular was rendered mild and soon thrown off when the inherited taint was combated.

Pharyngospasm.—Weill calls attention to the spasm in the pharynx liable to be induced by some insignificant lesion. It does not cause spontaneous pain but the children refuse to eat, and this acute pharyngism is quite a common cause of supposed lack of appetite. This may keep up for weeks or months, with transient intermissions. The child seems to lose the notion of eating. He is not only seldom hungry, but he seems to have forgotten all about eating. He accepts food and chews a mouthful, but does not swallow it, chewing it over and over. The spasm conditions are like those with erosion of the anus. The children affected were from 19 months to 9 years old. Sometimes catheterization breaks up the spasm at one sitting. Other cases may require two or three sittings with a few days' interval. He uses Bouchard rubber sounds, dipped in boiling water and then in glycerin, for the progressive dilatation. The child is then able to swallow at will. The spasm can also be combated with a cold water compress to the throat for thirty or forty minutes, and then massaging the throat. If the child shrinks from swallowing, the finger pressed on the trachea causes suffocation which starts a swallowing movement. These measures are not so certain as the sound. With a neuropathic tendency, success is sometimes attained by having a stranger feed the child, and sometimes it will soon be swallowing normally. In three cases the children had become so much debilitated that murmurs suggested heart disease. The children held the mouthful of fluid in the mouth and then let it drool away. They were convalescing from typhoid, and minute ulcerations were visible on the posterior wall of the pharynx. He touched the throat with cocaine and compelled these children to swallow fluid in abundance, and all the symptoms subsided.

Hemophilia.—Nobécourt describes some typical cases, and reiterates that the most effectual treatment to date is fresh horse serum and subcutaneous injections of 3 or 4 c.c. of a solution of peptone, 5 gm. in 100 gm. of water containing

0.5 gm. sodium chlorid. Three or four of these injections are made at two or three days intervals, repeating the series every three or four weeks. This was kept up for two years in one of the cases and the benefit was pronounced, although, as he reiterates, it seems to be impossible to cure hemophilia. The best we can do is to attenuate it.

Familial and Hereditary Exophthalmic Goiter.—In Harvier's case the goiter developed at 12, and the young man's mother, grandmother and an aunt on both the maternal and paternal sides had presented exophthalmic goiter. His sister had escaped. The tremor in his case had been noted from early childhood.

*Acute Appendicitis. A. Gosset and J. Berger.—p. 753.

*Tattooing in Therapeutics. L. Dufourmentel.—p. 755.

Emergency Appendectomy.—Gosset and Berger emphasize certain precautions desirable in operating in acute appendicitis, such as the warning that chloroform damages the liver which is already suffering from the pathologic storm. Spinal anesthesia is also dangerous, as the appendectomy may require changes of position.

Therapeutic Tattooing.—Dufourmentel refers to tattooing in the effort to render scars, etc., less conspicuous by punctate injection of a coloring matter to bring the tissues to resemble the skin around. His experiments have shown that an indelible and nontoxic pigment for white is available in the oxid of antimony or white of antimony, Sb_2O_3 , and for red in the iron oxids known as "earths," including ochre, and cadmium salts. The colors are mixed with alcohol and then diluted with distilled water, and a small area, not over 1 sq. cm., is covered with the pigment. This is pricked into the skin with a small instrument which has from three to six needles set close together. The other end of the instrument is finished with a spatula. The points should enter the skin for only half a millimeter, not deep enough to draw blood. When a drop of blood oozes, it washes out the color. India ink is used for black, and he has been gratified with the outcome of the black tattooing to fill in a gap in eyebrow or moustache. The results have also been truly excellent, he says, in cases of extensive white scars from burns in the face, tattooed with pink. The skin is washed off with ether and then with alcohol; iodine would interfere with the tattooing.

Arguments for Parasitic Origin for Psoriasis. L. Bory.—p. 487.

*Purpura in Typhoid. C. Roubier and P. Brette.—p. 488.

*Chilblains. H. Roziès.—p. 490.

Purpura During Convalescence from Typhoid.—Both of the two patients recovered, confirming the favorable prognosis which is the rule with tardy purpura in typhoid. The blood coagulated normally and the erythrocytes were not unusually fragile. The outlook is very grave when hemorrhagic syndromes develop early in typhoid.

Chilblains.—Roziès describes in turn the various methods of treatment in vogue for the relief of chilblains, saying that the aim with all is to promote the circulation in the capillaries and modify the lymphatic predisposition. Local measures which aim to relieve congestion and pain include elec-

tric light baths, hot air jets, exposure to the sun, film treatment as for a burn, massage and gymnastics of the legs. For the latter, the reclining subject lifts his leg as high as he can, holding it with his hands and flexing and stretching the foot and the toes, keeping this up for five minutes, and repeating every hour, working thus each leg and each arm each time. This modifies the circulation effectually. For direct medication, Comby advises a tepid bath, then rubbing with spiritus camphorae and, on retiring, painting with iodized glycerin (equal parts). Among the other procedures described is Jadassohn's treatment with baths: The part is soaked for ten or fifteen minutes in water as hot as can be borne, adding boiling water until the skin is very red, and doing this three times a day, wiping the part carefully dry afterward. Roziès gives a long list of other procedures that the practitioner has at his disposal for treatment of chilblains.

*Psychoses Cured by Intercurrent Infection. H. Damaye.—p. 501.

Psychosis Cured by Intercurrent Influenza.—In Damaye's two cases the psychosis was of the dementia praecox type, and had lasted eighteen months in one case and seven in the other. The mental condition returned completely to normal after an attack of febrile influenza in the first case and of infectious sore throat in the other. The patients were men of 20 and 23.

Policlinico, Rome

Aug. 3, 1919, 26, No. 31

*Injection of Arsphenamin on the Fascia Lata. M. Trossarello.—p. 937.

*Filtrable Viruses. R. Ciauri.—p. 940.

Arteriovenous Aneurysm in Thigh; Two Cases. P. Perazzi.—p. 945.

Injection of Arsphenamin on the Fascia Lata.—Trossarello was much pleased with the advantages of injecting the arsphenamin on the fascia lata instead of into a muscle. In 60 per cent. of the thirty patients treated with this technic the injections were painless or nearly so. In 25 per cent. there was a moderate reaction, and in 15 per cent. a sharp, painful reaction. Those in this latter group were all in the tertiary stage of syphilis. There never was any suppuration or necrosis at the spot, and he advises this epifascial technic as preferable to the muscular when intravenous injections are not practicable.

Filtrable Viruses.—Ciauri marshals the data already accumulated in respect to filtrable viruses, and comments on the conflicting state of our knowledge to date. Is it possible that certain bacteria pass through a filtrable stage in some phase of their development, he asks, or are we to assume that some filtrable virus happens along and suddenly mobilizes the latent pathogenic properties of ordinarily harmless bacteria?

Result of Operations on Trunk Nerves. Boschi and Perrone.—p. 385.

Research on Sensibility to Vibrations. C. Frank.—p. 387.

Adaptation of the Heart to Physical Strain.—Minerbi reviews a large number of recent Italian contributions to the physiology of the heart, and the way in which it defends itself against overstrain within physiologic limits. Among others Giuffrè has demonstrated that not only mechanical and hydraulic factors cooperate in accelerating the heart beat during physical exertion, but psychic, volitional, factors also cooperate, and likewise chemical factors, from waste produced by the physical exertion, and nervous factors, from stimulation of the accelerators and inhibition of the vagus. Minerbi has called attention to the isolated increased tonicity reaction in the different cavities of the heart as a sign of their functional capacity. Much of the recent Italian work on the heart has been true pioneer research, he explains.

*Coccidioides Immitis. A. M. Pedroso.—p. 193.

Relations Between Infant Feeding, Infection and Constitution. O. Chiapparelli.—p. 204. Cont'n.

Coccidioides Immitis.—Pedroso gives nearly six pages of literature on coccidioidal granuloma, and describes a case diagnosed as blastomycosis from which he cultivated *Coccidioides immitis*. It is easily differentiated, he says, by the fact that its reproduction is by sporulation and never by budding, while blastomycetes always grow by budding and never by spore formation.

October, 1919, **10**, No. 10

*Case of Blastomycetic Dermatitis with Epileptic Seizures. J. Mendes Pereira and F. Jacobs.—p. 217.

Blastomycetic Dermatitis with Epileptic Seizures.—Mendes and Jacobs state that the number of cases of blastomycosis in Brazil is growing constantly larger as physicians are learning to recognize it. In a case reported, the previously healthy young married woman developed a skin lesion in the right parotid region treated at first for eczema. The glands around suppurated, and by the sixth month there was a severe epileptic seizure and again the seventh month, and after this mild seizures of the Bravais-Jackson type recurred almost daily. The aura was always in the right ankle and there was paresis of the leg. The diagnosis had been in turn eczema, gout, syphilis, tuberculosis, and leishmaniasis of the skin until the microscope revealed the blastomycetes. Iodid treatment was then pushed but no benefit was realized, and the epileptic seizures continued while the skin lesions spread, with death in less than a year from the first symptoms.

Protozoan Parasites of Man in Paraná. C. Pinto.—p. 329.

*Treatment of Renal Dropsy. C. de Rezende.—p. 329.

Treatment of Nephritic Edema.—De Rezende comments on the rebellious nature of subacute and chronic parenchymatous nephritis; it usually resists all treatment unless it is of syphilitic origin. In a recent case a girl of 10 died in nine months from the first symptoms. In another case a youth of 16 had traveled far on the same road, and was bedridden from the enormous dropsy when he contracted influenza. After a week of a terrible struggle with the influenza, which had invaded the lungs, the diuresis increased and the renal dropsy melted away, the young man leaving the hospital without a trace of edema a month after the onset of the influenza. De Rezende quotes a similar case recently reported by Allbutt, with recovery after influenza. But Allbutt ascribes the recovery to his dietetic treatment according to Epstein's method, aiming to supply the system with an abundance of albumin to make up for the huge losses of albumin in the renal dropsy. De Rezende is convinced that the cure in these two cases was due to the intercurrent febrile disease which modified the osmotic tension in some way and broke up the abnormally inverted current of fluid from the blood into the tissues. In future cases of the kind de Rezende intends to apply treatment with injections of normal serum, by the vein or subcutaneously. This will supply the albumin to conform to Epstein's theory, while he expects that it will induce a salutary febrile reaction which will modify the physical or physicochemical conditions.

Palliative Operation for Cancer of Bladder. C. Estévez P.—p. 124.
Hemorrhagic Purpura. G. Valdés.—p. 126.

Yellow Fever in Guatemala.—In the course of this report of his experiences, Madrid states that three children, from 5 to 7, presented at first the same clinical picture as the adults, but ascarides issued from the mouth and anus, without feces. The children also presented convulsions, contractures and meningism, and one had vaginal hemorrhage. Most of the women had profuse uterine hemorrhages. One morning he was called to two adults presenting the identical clinical picture, sudden onset, high fever, pain in the stomach, and rapid pulse, but no albumin was to be found in the urine.* The next day one still had fever, with intense albuminuria, and the diagnosis of uremic-hemorrhagic yellow fever was confirmed by the further course. The other patient's urine and temperature were normal, and quinin then conquered her simple malaria. Madrid extols the advantages from autoserotherapy in the twelve patients given a single injection of the autoserum. But he warns that after the fourth day there are no antibodies, and hence the procedure is futile after that date.

*Myiasis. E. D. Cortelezzi.—p. 334.

Influenza. P. A. Etcheverry.—p. 339; A. Thomson.—p. 342.

Chronic Pseudo-Appendicitis.—Goyena tells of a case in which an emergency appendectomy was done for an "abdominal mirage" from pneumonia. He thinks that in many of the cases recorded as "chronic appendicitis cured by appendectomy," the cure was the result of the rest and hygiene during convalescence. A sign lauded as pathognomonic of appendicitis, the intense pain induced at the cecum when air is pumped into the rectum, was strongly positive in a recent case years after the appendix had been removed. In a large proportion of cases the disturbances return sooner or later after the appendectomy, as they are the result of stasis in the cecum, and the appendix is not responsible for them. Simple medical measures may correct conditions revealed by radioscopy and other modern exploratory methods.

Sanatorium for the Tuberculous.—Añon Suarez gives an illustrated description of what he calls the ultra-economical sanatorium unit, and the arrangement of several such units to form a sanatorium of 768 beds with 80 beds to the hectare. A row of four units form an obtuse angle open to the sunshine, with back to the cold winds, and the other sets of four units parallel these, with ample space between.

Myiasis.—Cortelezzi reviews the literature and reports two cases in which the maggots of *Chrysomya macellaria* were found in the ear or nasopharynx. In one case over 100 of the larvae were expelled from the ulcerated nose and pharynx after instillation into each side of the nose of 2 c.c. of benzoin, and the pharynx had been touched with it.

*Disqualifications for Matrimony. A. Stucchi.—p. 368.

Importance of Early Diagnosis of Tuberculosis. J. F. Mieres.—p. 376.

Origin of Univitelline Twins.—Deluca and Widakowich discuss the evidence on the cause of twin pregnancies from

one ovum, and say that there is much to sustain the assumption that this results from fecundation of the ovum by a spermatozoon with two heads. This assumption is sustained further, they say, by the fact that twin gestation of the univitelline type occurs mostly in syphilitized families. The spermatozoa in syphilis are more often of the double-headed and other anomalous types.

Syphilitic Sclerogummatous Dermatitis.—The excrescences on the foot had been developing for five years, and the Wassermann test was negative; after excision of the extensive hardened areas and specific treatment, clinically normal conditions were restored. The Wassermann reaction became positive later.

Ultraprophylaxis of Disease.—Stucchi discourses on the tragedy and absurdity of the present laws which lay so much stress on matters of property and land ownership in relation to marriage, and yet pay no attention to the really vital matters, whether the contracting parties are bringing loathsome disease into the family they are founding. He discusses the arguments for and against the forbidding of marriage to the chronically diseased, and urges this "ultraprophylaxis" as necessary from the legal and social standpoint as well as from the biologic and medical.

*Percutaneous Tuberculin Treatment of Tuberculosis. S. de Madrid.—p. 400.

Eugenics in the United States. V. Delfino.—p. 403.

Tuberculin in Minute Doses.—Gómez here continues his analysis of his experiences with almost infinitesimally small doses of tuberculin, as described repeatedly in THE JOURNAL in the last few months. He says that every one responds with a stimulation of the vital processes to injection of the bacillin, as he calls this many-million-times diluted tuberculin. This action is manifest within six or twelve hours. The reaction to tuberculin is always focal when there is a focus, the effect proportional to the dilution. This reaction may be in the form of an aggravation, from the production of lysins, or there may be marked improvement from the production of what he calls haptins. The latter denotes the beginning of the therapeutic action which terminates in immunity. By reducing the dilutions to the extreme limit, the lysin-producing phase is skipped, and we begin to realize at once the favorable, haptin-producing response. The ordinary tuberculin tests reveal merely that the subject is tuberculous. Tests with the tuberculin in this extreme dilution tell not only that the subject is tuberculous, but they locate the tuberculous lesion by the changes in the symptoms from it under the influence of the bacillin.

Obstetric Shock.—Iraeta remarks that the low blood pressure, subnormal temperature, exhaustion tachycardia, and syncopal condition sometimes noted after delivery should be regarded as typical shock, and be treated accordingly. Ether or chloroform may bring on acute insufficiency of the suprarenals in parturients with latent predisposition thereto, and hence he warns against the use of either, saying that nitrous oxid is free from this danger and should be preferred for obstetric cases. He quotes Bayliss' recommendations of gum injections preliminary to intervention, for persons predisposed to shock. The action of epinephrin, saline infusion, etc., is transient or unfavorable, but the Bayliss 6 per cent. acacia solution in physiologic saline increases the viscosity and osmotic tension while, he reiterates, there is no danger of anaphylaxis, hemoptysis or agglutination with it. The initial perfusion with 500 c.c. can be repeated in fifteen minutes and, if the blood pressure drops again, there are no contraindications to repeating the injections. Iraeta's practice in case of established shock is to give the intravenous gum injection and, if this is not effectual, he follows it with transfusion of blood. Warming up the patient is important; he has seen dogs in shock recover when warmed while the unwarmed succumbed. He warns against danger with intravenous injection of camphorated oil. His reliance other-

wise is on inhalation of oxygen, reclining horizontal, and absolute repose.

Antibodies in Hydatid Cysts.—Agglutinins were found in the fluid of two hydatid cysts in the liver in a child who had died from typhoid.

Proportionate Duration of Ventricular Systole.—That determination of the proportionate duration of the ventricular systole has, functionally, greater significance than the pulse rate, is the conviction reached by Brugsch and Blumenfeldt, after extensive research on the subject at the Berlin Charité. For the determination of the cardiac systole, phonocardiograms were made, recording the heart sounds. For control purposes, electrocardiograms were made simultaneously. The results of their investigations on healthy subjects showed that with increasing age there was a corresponding increase in the proportionate duration of ventricular systole (expressed as a percentage of the complete cardiac revolution). Sex, however, seemed to play no part. Although, in a general way, the proportionate duration of the systole increased with an increase of the pulse frequency, it was evident that no functional ratio existed. Especially significant was the finding that the proportionate duration of systole in healthy adults has a constant value after rest, and that the variation in different individuals is slight. The value as determined for both sexes in the age group 25-70 is from 33.5 to 37.5 per cent. (of the cardiac cycle); whereas pulse frequency varies from 50 to 78. The authors found further that in certain cardiac diseases; for example in aortic and in mitral insufficiency, the proportionate duration of systole increased with the severity of the disease, whereas in certain other heart diseases there was a decrease. The investigations must be carried further, but the authors feel that the marked diagnostic value of the determination of the proportionate duration of ventricular systole is already beyond question, and that it surpasses that of the pulse rate.

Modification of Benzidin Test for Occult Blood.—Gregersen has recently found that a frequent cause of failure in the application of the benzidin test is that too strong solutions of the reagent are used. Following Grundmann's idea, he reached the conclusion that many of the positive reactions in normal persons on a meatless diet may be explained by the fact that minimal traces of blood were mixed with the feces, which, because of the excessive sensitiveness of the reagent, produced positive reactions. Boas accepts the idea that the use of highly concentrated benzidin solution does lead to false diagnosis, and on that account approves, after careful trials, Gregersen's modification of the test. Gregersen uses a 0.5 per cent. benzidin solution, and instead of the easily decomposable hydrogen dioxid he employs barium dioxid, which is much more stable. Gregersen's method is described in detail, and Boas offers what he considers a further slight improvement. Boas admits, however, that in using the weaker solution very slight hemorrhages, though worthy of note, might go undiscovered.

Disturbances of Liver Metabolism.—The reason why the chemical processes in the liver have not awakened more clinical interest in the past is that disturbances in liver metabolism are difficult to determine. It has been difficult to differentiate between pathologic and physiologic phenomena, perhaps, because the pathologic phenomena are usually only quantitative shiftings. But Isaac thinks that these quantitative changes, while causing at first only partial changes of function, usually affect finally the action of the liver as a whole. The equilibrium of certain associated processes on which the normal metabolism of the liver depends may be only slightly disturbed, but in the aggregate a complex derangement of the liver functioning may thus be entailed. He finds that the most common cause of disturbance lies in

primary changes in carbohydrate metabolism, and illustrates this point by considering in detail various alimentary disturbances of glycogen metabolism. He shows how the liver may react in different ways to nervous and toxic stimuli, but that it is always a question of an exaggeration of some normal specific function.

Superposed Infectious Diseases.—Since the combined appearance of typhoid and dysentery is comparatively rare, Zondek reports several cases observed during the war. He has noted the tendency to consider such cases as atypical infections, whereas a more careful diagnosis revealed the presence of a mixed infection. Similar diagnostic errors might explain other so-called atypical diseases. Sometimes dysentery followed typhoid, sometimes the converse was true, if the statements of patients before entering the hospital may be accepted. The second infection began often during convalescence from the first. At other times the two infections ran parallel. The course of the dysentery offered nothing peculiar. Only one case was fatal. He mentions as significant that in one patient one week after defervescence of paratyphoid B, *B. dysenteriae* was found in the stool, though clinical symptoms did not appear until four days later. This finding evidences the fact that dysentery patients eliminate dysentery bacilli during the incubation period. Four paratyphoid patients eliminated *B. dysenteriae* during convalescence without showing clinical symptoms of dysentery at any time. It was often difficult to demarcate the typhoid from the dysentery, for typhoid, and especially paratyphoid, may often present a picture resembling dysentery. There was no evidence that the course of the typhoid was influenced by the dysentery. On the other hand, the dysentery was brought to an unexpected termination by the typhoid. However, paratyphoid B could not be shown to have any effect on the dysentery. Whether paratyphoid B was influenced by the dysentery could not be definitely shown, but the course of the paratyphoid B was short and uneventful. Paratyphoid A could not be shown to have been affected by a previous dysentery, but the course of the disease was lighter than usual.

During synchronous epidemics of typhus and recurrent fever about 1,000 typhus patients and 150 recurrent fever patients were treated. In twenty cases typhus followed recurrent fever. The severe and stormy course of the typhus was doubtless due to the preceding attack of recurrent fever, which had left the patient in a weakened physical condition and had doubtless damaged the central nervous system. In six cases the typhus set in after the first attack of recurrent fever. During the course of the typhus the spirochete of relapsing fever was not found in the blood. There was no second attack of the recurrent fever in these six cases, but the other patients with recurrent fever followed by typhus had two or more attacks of the former.

Correspondenz-Blatt für Schweizer Aerzte, Basel

*Smallpox and Vaccination. G. Sobernheim.—p. 1849.
Neuroses and Psychoses Among the War Interned. A. Repond.—p. 1858.

*Porphyrinuria with Paralysis. W. Löffler.—p. 1871.
Anscultation with Two Phonendoscopes. G. A. Römer.—p. 1879.

Smallpox.—Sobernheim expatiates on the importance of an early diagnosis of smallpox. The extremely fine granula found by Paschen in all the smallpox cases he examined requires great skill in the technic for its discovery, but it most certainly seems to stand in some relation to smallpox, as also Guarneri's cell inclusions which can be reformed in the rabbit cornea inoculated with pustule contents. This test also requires a complicated technic, but Paul's method is simple and rapidly instructive. With this, the scarified rabbit cornea is inoculated with contents of the suspected pustule or with secretions from nose or throat, and in thirty-six to forty-eight hours there is a macroscopic reaction, the cornea around remaining normal while minute elevations can be seen at the infected points. If the eyeball is placed for a short time in mercuric chlorid-alcohol, the cornea turns gray while the minute swellings show chalky white. This kind of reaction is seen only with smallpox or vaccine virus, but

negative findings are not conclusive. With this and other tests, it has recently been demonstrated, he adds, that the virus is found in the nose and throat early in the disease, and that the disease can be transmitted by droplets, but no evidence of healthy carriers has been discovered as yet.

Porphyrinuria with Ascending Paralysis.—Löffler adds another to the fourteen cases of acute porphyrinuria on record; his case is the fifth with symptoms of acute ascending, lax, purely motor paralysis. No cause for the porphyrinuria could be discovered in the previously healthy farmer's daughter. It is curious that women formed 92 per cent. of all the cases of the acute toxic form, and 78.5 per cent. of the acute idiopathic form. Necropsy failed to reveal in his case any pathologic changes in brain, cord or peripheral nerves. The urine averaged 0.065 per cent. porphyrin; in one day's 400 c.c. urine there was 0.26 gm. In chronic porphyrinuria the range is from 0.17 to 0.57 gm. The porphyrin answered to all the tests, confirming that a single form of porphyrin is found in both the chronic and acute cases. The stools also showed the spectrum for porphyrin; this is the first time, he says, that it has been found in the stools in acute porphyrinuria. None could be detected in the blood. At first abdominal symptoms predominated, but after six weeks the paralysis developed and proved fatal in less than a week.

- *Nerve Anastomosis for Facial Paralysis. Id.—p. 141.

Acute Idiopathic or Fulminating Psychosis.—Ladame reserves this name for acute insanity, with a rapidly fatal termination, which presents a characteristic clinical course and histopathologic changes *sui generis*, indicating acute inflammation of the mass of the brain. The article is based on eight cases, and emphasizes particularly the intense motor restlessness and the rapid desiccation of the tissues and early cachexia, with signs of grave general nutritional disturbances, profound mental confusion and death in one or two weeks. He suggests that by combating nutritional disturbance at the start we might ward off the disease. The lipoids, especially the lecithin, seem to be mainly involved, and treatment should aim to arrest the disassimilation, which would remedy also the derangement of the water balance. This psychosis is rare, forming only 0.25 per cent. of the 3,181 insane at the Bel Air asylum. (Ladame's untimely death has recently been reported.)

Chemical Differentiation of Sections of the Brain.—Landau calls attention to the fine contrast staining obtained by the chemical reaction when a specimen is stained in turn with iron salts of a higher and lower valency. It is especially instructive for sections of the brain. He places them for a few minutes up to an hour in a 1 or 2 per cent. solution of ferric chlorid and then rinses and transfers to potassium ferrocyanid. If the stain is too deep, it can be decolorized with ammonia and stained over again.

Congenital Luxation of the Atlas.—Demole found at necropsy of a woman of 30 who had never displayed any nervous symptoms, motor or sensory, that there was forward subluxation of the skull on the spine, and the spinal cord was crushed out of shape. He ascribes this luxation to flexion of the neck at the third month of fetal existence, for reasons which he describes, and comments on the way in which the fetal spinal cord adapts itself to such injuries. The atlas had grown to the axis beneath.

Electric Stimulation of Motor Functioning of the Stomach Wall.—Bircher reports experimental and clinical experiences with various forms of electricity applied to the vagus innervation of the stomach wall and also directly to the wall. The details in seventy-five clinical cases are tabulated. They

testify to the importance of the neurotic factor in ulcer. Another practical point learned is that when the surgeon is unable to discover any anatomic basis for the disturbances, electric tests will reveal pathologic conditions when such exist. The sensation from the electricity was always referred to the electrode on the skin, the stomach itself not apparently feeling it. The excitability of the stomach was tested directly in the operative cases. The threshold grows lower from the cardia to the duodenum, and the excitability is greatest opposite to or just below an ulcer.

Retrogasserian Resection of Trigeminal Nerve for Neuralgia.—Perret reports the excellent outcome over three years to date in a very severe case of trigeminal neuralgia treated by severing the nerve back of the gasserian ganglion. This entails ascending degeneration of the centripetal fibers of its sensory root, and cures the neuralgia, while there is no danger of the neuromyolytic keratitis liable after gasserectomy, as the sympathetic fibers passing to the ophthalmic nerve are left intact. The case is illustrated.

Grafting the Facial on the Hypoglossal Nerve Cures Facial Paralysis.—Perret's illustrations show the fine result realized in a case of total facial paralysis in a young woman by total end-to-end anastomosis of the hypoglossal and facial nerves. Seven years later no asymmetry can be detected and there is scarcely a trace of lagophthalmos. One half of the tongue showed a tendency to atrophy at first, but it grew less apparent, and speech is perfect. The only suggestion of associated movements is a slight fibrillary tremor in certain regions in the cheek but she can control even this when she is not tired.

Incipient Cancer or Atypical Proliferation of Epithelium?—Benthin gives photomicrographs of seven cases in some of which even microscopic examination of practically the whole uterus failed to decide for or against malignant disease.

Bile Serologic Test for Cancer.—Dietrich has found that the natural hemolytic action of bile can be checked by addition of normal serum, but that serum from women with genital cancer allows the hemolysis to proceed unchecked. He proclaims this as a new biologic test for cancer, and reports that the findings with it were positive in 95 per cent. of forty-one cases of genital cancer in women, while they were positive only in 5 per cent. of the 121 noncancer women, and in these positive cases there were inflammatory processes. He explains the reaction as due to destruction of the albumins in the cancer serum, and declares that it is a useful guide not only in diagnosis but for the prognosis and in control of the results of operations and raying. He uses for the test a reliable element of bile, sodium taurocholate, in a 0.5 per cent. solution in physiologic sodium chlorid solution in a set of twelve tubes, ranging from 0.28 to 0.17 c.c. of the taurocholate and filled with the saline to 1 c.c. To each is added 0.01 c.c. serum, with a parallel set containing 0.01 serum from healthy subjects. After thorough mixing he adds to each, 1 c.c. of a 2.5 per cent. suspension of erythrocytes from umbilical-cord blood of newly born infants, caught in sodium citrate, 1:10, and thoroughly rinsed with saline, centrifuging three times. The reaction is estimated after thorough mixing and the tubes have been incubated at 37 C. for two hours. In the normal serum tubes there is no hemolysis, while in the cancer serum tubes hemolysis occurs. Dietrich reviews the literature on biologic tests of cancer, remarking that none have come near to standing the test of time except the miostagmin reaction and, possibly, Abderhalden's.

Operative Recurring Inflammation of Internal Genitals.—Fraenkel reviews the ultimate outcome in 1,305 cases of recurring inflammatory gynecologic disease at Frankfurt, all

given medical treatment but ninety-seven. This operative group includes thirty-eight with radical abdominal total extirpation, and the final verdict is decidedly in favor of this from every point of view.

Treatment of Genital Prolapse.—Martin reviews the various operative methods that have been devised to cure genital prolapse, and remarks that even the best planned and best executed operations have some failures on their record. The general condition is an important factor. Infantile, thymus-lymphatic and constitutionally inferior tissues cannot always be relied on as a permanent support, even where the conditions at first seemed perfect.

Pain in Gynecologic Disease.—Opitz warns that even with unmistakable hysteria or neurasthenia there may be local causes for pains. Careful search for these causes will reduce more and more the number of cases of purely psychic pains, although never doing away with the latter entirely. Among the causes liable to be overlooked which may be responsible for pain are (1), clumps of ascarides entailing local spasm of the bowel; (2) enlargement of veins in the pelvis. The phlebectasia can sometimes be palpated. In several cases he was able to cure tormenting pains of long standing by ligation of the enlarged vein. Pain from this cause usually comes on when lying on the back. (3) Kinking or stenosis of a ureter or traction from bands is liable to cause pain; sometimes catheterizing the ureter may straighten it and put an end to the pain. (4) Pain in the sacral region may be due merely to fatigue of the dorsal muscles; this pain comes on in the course of the day and is relieved by repose. Or sacral pain may occur from stretching of the ligaments of the iliosacral joint, and the ligaments are found tender, especially in women with oblique pelvis. Massage, gymnastics and strengthening measures may help. (5) A further cause for pains may be found in retroperitoneal tuberculous glands. Kneise has cured several such cases by operation or tuberculin treatment. (6) One of the most frequent causes is abnormal movability of the cecum or sigmoid flexure, or their being bound down by bands. He has cured numbers of patients by correcting these conditions, especially the adhesions at the sigmoid flexure. These are particularly liable to cause disturbance during pregnancy and the puerperium. He has found these adhesions in 95 per cent. of the cases, but they do not always cause pain. In several cases he did not cut these bands at the laparotomy for other cause as they had never caused disturbance, but they began to make trouble later.

Opitz now has a record of large numbers of cases of pains in the left abdomen permanently cured for years by merely breaking up these adhesions at the sigmoid flexure or cecum; they are usually connected with—possibly extinct—disease in the genital organs, and the pains are generally mistakenly ascribed to displacement of the uterus. They persist after operative correction of the displacement, or are even aggravated by this as the traction is made greater. Ordinary rheumatism affecting the pelvis and sacrum may be responsible for the pains in some cases; the tonsils should be examined. He emphasizes further the importance of distinguishing between the stimulus that causes the pain and the brain that perceives it. By psychotherapeutic suggestion and general strengthening measures we may be able to reduce the acquired oversensitiveness of the central nervous system, and thus cure from another angle.

Suprapubic Cesarean Section.—Banmm has now a record of 223 cases of contracted pelvis in which delivery was by sectio suprapubica. The mortality was 2 per cent. in the clean cases and 13 per cent. in the febrile cases. In two cases the operation was repeated at a later pregnancy and in another case three times. The prospects for the children are the same as with the classic technic. In over 59 per cent. of the cases, the operation was extraperitoneal. The great advantage is that the whole operation can be concluded at once and the uterus sutured. This suprapubic technic should not be considered for febrile cases with fetid amniotic fluid, or with an interval of twenty-four hours since the escape of the fluid.

Ventrifixation of the Vagina.—Fraenkel reports two cases, and cites others from the records, of ventrifixation of the vagina in treatment of recurring prolapse after hysterectomy or with primary prolapse, leaving the sound uterus intact, or removing the diseased uterus. The operation is simple and easy and all are surprised at the effectual way in which it counteracts the tendency to prolapse, while it is not liable to interfere with pregnancy later.

Chronic Ulcer of the Vulva.—Heinsins has had four cases of extensive inoperable destructive ulcerative processes starting in the vulva, with multiple fistulas. Great relief was obtained from fixation to the abdominal wall of the sagging genital organs and bladder.

The Eclampsia Question.—Dienst announces that his experimental and clinical research has settled once for all that the blood in eclampsia contains an abnormally large proportion of fibrin-ferment. This excess of fibrin-ferment explains the edema of pregnancy, pregnancy kidney, and eclampsia as the various degrees of intoxication with fibrin-ferment, as he describes in detail. In many hundreds of blood specimens the findings were constantly concordant in the deficient production of antithrombin in the eclampsia and pregnancy cases, and the consequent overloading of the system with thrombin. He announces the constant finding of fibrin-ferment in the amniotic fluid as early as the second month in normal pregnant women, but in these normal women no free preformed fibrin-ferment was ever found in the blood plasma. For this and other reasons he assumes that the maternal placenta is the source of production of the fibrin-ferment. Treatment should aim to relieve the spasm of the blood vessels caused by the excess of fibrin-ferment. Small repeated doses of narcotics, as in Stroganoff's prophylactic treatment, accomplish this, while venesection lowers the blood pressure and starts up the circulation and the production of antithrombin in the liver. Leech extract may also aid in combating eclampsia, and rupture of the membranes may reduce the pressure so that the liver may have better circulation, and aid in combating the toxic action. As the placenta keeps producing more fibrin-ferment, it should be got rid of quickly. Nolf states that acid drinks promote production of antithrombin, and hence the pregnant should be encouraged to drink freely of lemonade, etc. The pregnant naturally craves acid drinks and foods. A fat-poor and albumin-poor diet tends to keep down production of fibrin-ferment. This has been evidenced in the lesser number of cases of eclampsia during the last few years on the restricted war diet. In conclusion, Dienst mentions the recovery from impending eclampsia in a case of the severest form of pregnancy kidney in which he gave lemonade in large amounts and two subcutaneous injections of antithrombin in the form of blood from a healthy pregnant woman near term.

The Kielland Forceps.—Küster reviews some recent publications on the Kielland forceps and his own experiences with it, his conclusion being that these forceps and the method of their introduction form the most important progress that has been realized in instrumental obstetrics for many years.

*Cancer of the Rectum. P. Bull.—p. 1233.

Clinical Study of Influenza Pneumonia. R. Hatlehol.—p. 1310.

*Isolated Disease of Scaphoid Bone. E. W. Koritzinsky.—p. 1332.

Cancer of the Rectum.—Bull tabulates the details and outcome in 4 cases in which merely the malignant tumor was excised, 18 with amputation of the rectum, 2 with amputation of the sigmoid flexure, 13 with resection of the rectum, and 6 with resection of both rectum and sigmoid flexure. His historical sketch of the subject and his analysis of 71 personal cases of cancer of the rectum have convinced him that an exploratory laparotomy is practically indispensable, and that local anesthesia, especially sacral or parasacral anesthesia, offers many advantages and averts the danger of collapse and of complications on the part of the lungs. The tragic feature in treating cancer of the rectum is that the attempt to leave the anus continent often compromises the success of the intervention. He warns further that the only way to avoid gangrene of the intestine stump when it is drawn down is to ligate the superior hemorrhoidal artery above the mouth of the branch from the sigmoid artery. No action from roentgen or radium rays was apparent in the few cases rayed. Of the 39 who survived the radical operation, 17 lived for an average of eight and a half years, including six with survivals of from twelve to twenty years; 2 died from intercurrent disease after one and 2 after seven years and 16 of the others succumbed to metastasis or recurrence within five years. Two succumbed to peritonitis following an attempt to close the artificial anus. The permanent cures thus formed 30.8 per cent. of the 39 who survived the operation or 27.3 per cent. of the 44 operative cases.

Isolated Disease of Scaphoid Bone of Foot.—Koritzinsky reports a case of Köhler's disease, and compares it with the forty-nine cases on record. The prognosis is favorable; all the children outgrew the disease in from a year and a half to two years and a half, but recovery is materially hastened and suffering avoided by wearing a firm immobilizing bandage with a flatfoot insole. No operation should be considered. Sometimes the lesion is accompanied by a similar one in the patella, and it may be bilateral. The symptoms are pain and tenderness at this point, and the child steps on the outer edge of the foot. The lesion has usually a traumatic factor, but it may be merely a defect in development from some nutritional disturbance, like Kienböck's traumatic malacia of the os lunatum and Calve-Perthes' similar hip joint anomaly.

Treatment of Diabetes in General Practice. H. C. Hagedorn.—p. 1939.

Functional Tests of the Heart.—Secher refers to tests that are simple enough for office and house practice. He commends in particular the Katzenstein, Rehfish and Schrumph methods. Schrumph states that with a normal heart the pulse returns to its former beat in four minutes after slight exercise, such as bending the knees ten times. Katzenstein's test is the difference in pulse and blood pressure before and two minutes after digital compression of the femoral artery for two or two and a half minutes. A rise in blood pressure and slower pulse rate indicate normal condition. An abnormally high rise in blood pressure is found with arteriosclerosis and hypertrophy of the heart. No rise in blood pressure indicates weakness of the heart; if the pulse is not modified, the weakness is slight, but if the pulse grows faster the heart must be regarded as decidedly insufficient. A drop in blood pressure with accelerated pulse indicates severe insufficiency; it is proportional to the degree of each. This test can be applied to the reclining patient, and Secher's experience with it in fifty cases demonstrated its approximate reliability. In some cases it excluded organic heart disease, and the course later confirmed its findings. The Rehfish test is by auscultation before and after bending the knees ten times; Bock's differential stethoscope eliminates the personal equation in estimating the findings. Bull expresses surprise that this stethoscope is not used more.

THE SOCIAL TREND IN MEDICINE*

GEORGE DOCK, M.D.

ST. LOUIS

Before the war, a new era made itself known in many ways; but medicine, especially in the United States, either held aloof or, at any rate, did not actively face the facts. Many things included under the term socialization affected medical practice as well as medical study. In England, several years before the war, the new course affected the profession abruptly and without preparation in the form of the insurance laws. Because of the strong similarity with political tendencies in this country we should have taken more interest in that movement in Great Britain. I do not intend to enlarge on details now, but mention the incident as an illustration. As the editors of the *Revue de médecine* remark in announcing some changes in the plan of that sound and representative journal, "medicine is becoming less academic and speculative, but more physiologic and social."

INDIVIDUALISM AND DEMOCRACY

Many foreigners, including the most penetrating as well as the most sympathetic critics of our political life, have emphasized the great danger of our satisfaction with a low level of culture; while those who are not partial to democracy in general look on it as a necessary by-product, and one that might serve as a warning to other nations less advanced in personal liberty. Those of us who are believers in democracy and those who wish to excel in any way, especially in the so-called practical lines leading to financial success, value the boundless opportunity given to individualism in America and have long refused to heed the pessimistic assertions of those who see in these opposing but related tendencies—individualism and democracy—a serious menace to the national life.

The satisfaction with unbridled individualism has much to do with some of the things most shocking to an impartial observer, whether exchange professor or recent proletarian immigrant. In no other country called civilized is life held so cheaply, as shown by the indifference to homicide in all forms and to accidents of all kinds. Murderers go uncaught or, if caught, unpunished; lynchers, equally lawless, never give a thought to punishment, because they know it will not be meted out. Homicide is not the only neglected wrong. Thievery of all grades, be it that of the simple footpad or the embezzler of bank funds, of the payroll

cash or automobile bandit, is equally undetected and unpunished. Life and property are not everything. Grade crossings of railroads, even in the most fashionable streets of large cities, resulting in many accidents, are but the logical companion-pieces to roads, such as no other civilized land has had since the end of the eighteenth century. It is characteristic of our fondness for exaggeration and mockery that we give to the worst of these the name of trails and of highways. Add to these dangers the smoke nuisance in almost all cities, the dirty streets and dirtier alleys, the unnecessary and wholly unprotested noise of the streets, which affect health and efficiency, and we have an outward form of civilization that must shock all contemporary visitors or future historians.

The practice of lynching seems to contradict the individualistic tendency so characteristic of the American people, but in fact it does not. The individualist is a strong and aggressive character who forces a way to success in spite of obstacles. There are, however, many persons who are too indolent and too lacking in initiative to become conspicuous; with little business of their own they have too much time to devote to that of others. From this and their suggestibility to evil, they form the mobs that, like some other low creatures, are always ready for mischief. The inertness of the officials whose business it is to apprehend malefactors is explained by the fact that such officials are chosen largely from the very element concerned in the violation of law or of peace. Even the higher officials, prosecuting officers and judges have the spirit of the mob rather than that of the guardians of the law and of the dispensers of justice. This explains why a policeman who actually sees a misdemeanor or felony will usually do nothing unless some bystander, especially the victim, promises to prosecute. It explains why prosecuting attorneys, the name illustrating the etymologic law "lucus a non lucendo," do not bring to justice those who ostentatiously violate medical practice laws, liquor laws, misbranding laws and many others. It makes clear why even federal officials, who have the function of enforcing food laws, try to base their legal actions on the testimony of physicians, dealing with more or less disputed chemical and physiologic questions, rather than on the plain legal phases of the case. Of course, another explanation is often given for all these derelictions of duty—dishonesty or graft—but that is not necessarily true. The test of war has shown that here, as in other countries, individualism is not essentially bad. On the contrary, the good which it accomplishes far outweighs the bad, and the latter can be kept down by education and the proper social adjustment. The passive, suggestible

* Read before the biennial international convention of Nu Sigma Nu, New York, Nov. 29, 1919.

spirit is always bad. In a weak state it makes slackers; in a strong one, it may produce efficiency, but is then a source of danger to its own country, as well as to others. For it, too, education is the remedy, but it must be a vigorous and definite education.

OUR LACK OF COOPERATION

One of the most glaring examples of lack of cooperation is shown in the state laws for medical licensure, or, in short, the medical practice laws. These laws have for their sole object the furnishing of well qualified physicians, and the exclusion of others. After hard work for nearly half a century, and less strenuous efforts for a longer time, the laws of most states act chiefly to prevent physicians from moving from one state to another, which, for climatic or other personal reason, one might prefer. In few of the states are the examinations so superior to others that the tests vary essentially from those in others. The citizenry does not care whether a physician has come from another state any more than in the case of a preacher, engineer or trolley driver. The quasi-excuse for such a state of affairs is that our form of government, the police power in relation to the states, etc., obliges us to submit to this absurd condition, which affects also such other details as marriage and divorce, taxation, etc. So far from being a valid excuse, this is only a confession of legal and political incapacity. It illustrates another fact in the ease with which we make laws, although every one knows that whereas some of them—or some details, like the practice laws—are observed in certain respects as if gospel, others are dead letters from the time they receive the governor's signature! so much so, that hundreds are unknown even to those who have the duties of making, signing and enforcing them. As Kipling says of the American spirit:

The cynic devil in his blood
That bids him flout the law he makes;
That bids him make the law he flouts.

The law officer, when accused of inertia, throws out a smoke screen by asking for still more laws.

Just as the country was getting into one of its frequent periods of financial and industrial depression, the war came; and although that form of intellectual dishonesty that calls itself idealism tried to keep us out, it was obvious from the beginning that we should have to fight for everything we had gained—life, wealth and honor, probably for civilization itself—with the certainty of losing something.

When war came, the weaknesses of the national fabric soon began to be disclosed. Notwithstanding our strong individualism and energy, our skill, ingenuity and industrial organization, the low average ability and lack of cooperation were seriously felt in many lines, and especially in those relating to the national security and the continuance of our traditional policies. And this proved to be true not only of such large matters as universal service and taking part in European politics, but in the more selfish questions of freedom of opinion and speech, of the use of spies and informers, of personal liberty in regard to wine and beer, and many questions of taste rather than of ethics or laws.

In spite of all these drawbacks we played an active part in the war, and one of signal honor in hundreds of ways. The experiences of the epoch can hardly be evaluated yet, but some of the lessons are already evident for those who wish to consider them.

PROBLEMS OF THE TIMES

At the beginning, when bodies and dollars were being poured out, there was the same pathetic confidence in a coming intellectual and moral renaissance as is doubtlessly always manifested when a nation goes to war. It was so in a less glorious war still within the memory of most people now living—the Spanish-American War. There was a general elevation of soul, even on the part of those who objected to the manner of beginning war, with high hopes of a mighty advance in all directions. It was assumed that with the courage of those who ventured all, with the self-sacrifice of the wives and families of the fighting men, a real and permanent exaltation above previous levels would take place in intelligence, in politics, in business and in public service.

Doubtless in individual cases there was a new birth or a moral exaltation that will continue; but in general we have fallen back into the old ruts, while some new traits, brought out or accentuated by the exertions or readjustments of the effort to win, have shown themselves to be even more threatening than the schemes of kaiser or German general staff.

One of the outstanding phenomena of the struggle was the important part played by experts, by men and women of scientific training, in medicine as much as anywhere. Medical men wholly prevented many of the plagues that in former wars decimated armies and devastated civil populations. They saved countless limbs that would have been amputated in previous wars; they restored minds unhinged by physical and mental shocks. The destructive pandemic of influenza that began before the end of the war and lasted long after hostilities ceased, may seem to lessen the credit due the medical service. This really emphasizes the value of medical science in the other cases mentioned. The misinformed sometimes assert that lessening of infectious disease in recent years is due to the advance of general and personal hygiene, but the truth is that each infection requires special measures, which can be taken only when the vital peculiarities of the infecting germ are known. Influenza in this respect is far behind many other diseases, such as diphtheria, smallpox, tetanus and typhoid fever, and it will probably require the labors of many investigators, working from various angles, to solve the problems of influenza and enable us to check its spread and danger. That the difficulties will be solved no one can doubt, and as in other cases, the necessary measures, no matter how costly, will be cheap in the end.

During the war, the resources of trained minds were so striking, the practical results in hundreds of directions were so real and so important, not only in medicine, but in every scientific line, physics, chemistry, physiology, bacteriology and serology, that one might have expected that those who accomplished such results would be hailed as the most precious and indispensable members of the commonwealth, and that they would be showered with everything necessary for their future work and material comfort.

But again history repeated itself: The men who accomplished the greatest destruction of life get all the glory and all the rewards possible, the physicists, physiologists, and the like return to their meager salaries and their poorly supported work. On all sides, while the struggle was on, it was asserted that since education had shown its value (with the imputation that it had not in dull times of peace) it would be easy to get the requisite financial means. That art and

science would no longer have to go after bread seemed almost an axiom.

Well, the war is over—for some purposes, such as selling beer, if not for others, such as digging coal—and what is the result? A few rare souls, as I said before, retain the exaltation they felt at first. The mass of the citizenry went back to the same old selfishness, the same indolence, the same indifference, the same carelessness. Many have gone backward physically and mentally, and show an intense ennui, a definite relaxation of physical and moral fiber. We see general lack of thrift and a widespread extravagance coupled with the desire for easy money, whether by raising to an exorbitant height the price of labor and commodities, or by the simpler methods of expropriation and printing of fiat money. The method of raising prices of labor or goods has been so successful in America that the Bolsheviks of Russia must regret the danger and bloodshed they risked when they followed the cruder method.

We are at present too much engaged in keeping our heads above water to know how serious the danger is. When Germany began her gamble of *Weltmacht oder Niedergang*, it was clear that the downfall threatened, not only the reckless adventurers who struck the blow, but civilization itself. Nor must we think that the results still to come can be no worse than those that followed the break-up of the Roman Empire. Just as civilization is so much more complex in almost all lands, and populations are so much greater all over the world with a resultant accentuation of the struggle for existence, and just as the means of destroying life and property are so much more effective than before, so may the shock, the destruction and the period necessary for recovery be much greater than ever before.

Very instructive are the intellectual camouflages that have appeared but have excited little comment. When the draft began and the records as to the large number of illiterates were made public, much surprise was expressed. Yet the facts and figures were accessible to everybody and had frequently been set forth by economists and educators. Nor is it strange that in the year since the armistice was signed no serious effort has been made toward bringing the literacy, even among native Americans, up to the level of civilized Europe.

Before the war the United States was fondly spoken of as the "melting pot," and "Uncle Sam" was figured as a benign pedagogue illuminating the soul of the benighted foreigners who throng to our shores. Since we found that the "melting pot" does not transmute the immigrant generation, we have no better way to improve it than by deporting it, without giving it time to learn English, or without getting the aid of the several hundred foreign language papers in setting forth our ideals, aims and laws. Much money was spent in propaganda to make bad Germans worse in their own country; very little to make Americans better in ours.

The great increase in the number of students at colleges and universities may be looked on as evidence of a desire for learning, but I am not at all certain that this is so. Large classes have been observed before, corresponding with times of financial stringency. Many people, and especially the families of salaried employees, find themselves now in that condition, and may furnish part of the number; others may be in affluence, and enter institutions of learning in order to get what social prestige may accrue from

that association. Among the congratulatory notes in the press about large classes, little appears in regard to another side. Before the war, the colleges and universities in many instances had insufficient teaching forces. With the increased cost of living many teachers have gone into other vocations, and their places have often been filled by less capable persons. The change of vocation is interesting. The war not only emphasized the importance of the expert, but it also showed how men of talent can rapidly master new subjects and make themselves, as it were, experts in other, and sometimes unrelated, lines. Not only may an economist become a successful banker; a physician, a zoologist or a modern language instructor may become a leader or an administrator in some industrial line. Universities see the danger and are making praiseworthy efforts to increase funds for salaries; but in the meantime the large classes and overworked and underpaid teachers must get on as best they may.

Since the war, a curious lowering of entrance requirements has threatened university scholarship. For some years adherents have been gained for the belief that education means not so much mental discipline as the cultivation of branches that are not disagreeable to those who take them. So now it is proposed that, in place of giving the matriculant an opportunity of showing his acquaintance with Cicero and Plato, with geometry and history, he must be familiar with even lesser stars in the "movie" constellations, and be able to tell whether a certain low priced motor car is made in Detroit, Flint or Toledo. I have seen the possible results of this foreshadowed in my daily work. In speaking before certain kinds of patients I have long had the habit of using terms like "psyche" and "cor" when inquiring about functions of brain and heart, frequent objects of morbid introspection to such patients. In the last few years I find that either no one in the class, with two years of college work, recognizes the word, or if he does he is not willing to embarrass his classmates with an exhibition of such antiquated mental lumber.

So we are passing through an era in which many traditions, beliefs and customs are in the scrap-heap or the melting pot. Those that survive must be treated by people, many of whom have had their mental faculties exhausted or unbalanced by the fatigues and shocks of the long struggle. Reconstruction will be slow at best, and can be successful only if the whole subject is worked at with all possible knowledge. A century and a quarter ago, Lavoisier, one of the greatest geniuses of France, who had given many proofs of the practical value of the scientific mind, was condemned to the guillotine, with no good reason, according to sober views. His reprieve was asked for on account of his scientific eminence, but it was rejected on the ground that the republic "had no more need of savants." Let us be sure that in our time the same cannot be said, or even subconsciously supposed.

There are some reasons for an optimistic view in this respect. One is the continuation of the work of the National Research Council, one of the most valuable auxiliaries of the government produced by the stress of war. With Henry A. Christian at the head of the medical division we may anticipate solid results. Another is the reconstruction work carried out under the direction of the Public Health Service. There can be little doubt that a demonstration of the practical value of this work on a large scale will impress every one that provision must be made for the wrecks pro-

duced by industrial accidents—wrecks very often quite as much the result of devotion to duty as those produced by war. With such examples we can hope it will soon be impossible to say of Congress, as Edward Everett wrote to William Beaumont in 1834: "The great difficulty lies in the theoretical objection to the appropriation by Congress of money for any scientific or philanthropic purpose whatever."

PROBLEMS CONFRONTING PHYSICIANS

We as physicians are concerned in innumerable social problems, along with other intellectual workers and handicraftsmen. We also have our special problems, depending on the close relation of medical advances with general industrial and social questions. Some of these arise from the new conviction of the need of cooperation in many lines of activity, the struggle for the extension in every direction of trades unionism, the tendency to strike in various forms and especially on a large scale. Others arise from the many manifestations of conscious and unconscious socialism already present, with the promise of still more serious problems should the radical movement reach the stages reported, incorrectly in many respects and imperfectly no doubt in all, in Russia and Hungary. The fact that a strike may assume the proportion of a monopoly has recently been shown, but has barely been mentioned by those who should do so.

Without wishing or intending to pose as an oracle, let me touch on a few of the problems:

Health insurance, with its reliance on the medical profession for the most important part of the work, has been widely discussed and warmly advocated, especially by nonmedical people. On this question there is an enormous experience in other countries, and it would be well if we insist on a study of such experiences and an equally thorough study of the differences in conditions in those countries as compared to our own, before we encourage such a project or take part in making laws concerning it.

The little work of David McKail and William Jones, recently published by the Fabian Society, illustrates some of the weak points of such plans. As a review in the *London Nation* (Oct. 25, 1919) shows, the English insurance act "was forced on the medical profession without its acquiescence and without its voluntary help; the act was brought to birth amid a mass of bargaining and trickery, the spirit of which still hangs about its administration (after eight years)." These comments remind one of the conditions under which even the most meritorious changes of law are brought about, and recall the dishonesty associated with the passing and application of the Lever act. The British reviewer goes on to point out the lack of facilities, including hospital care, expert opinion and surgical operations, under the operation of the insurance act. We can see how, with our more scattered population, the conditions in our country are even more difficult than in Scotland. The crux of the argument for the new system is based on the cost of operation, while the most salient point in this depends on the elimination of motor cars and the reduction of physicians' salaries to half their present income. In other words, under socialization, as under the old system, the physician's welfare is the last consideration. The proposal illustrates the inconsistency as well as the lack of humor of soviets. Their cry is mines for miners, railroads for railroad unions; why not patients and pay for doctors?

The socialization of medical and sanitary measures has already made some headway in the United States. I think it may be said that this consists essentially in having all public medical and sanitary affairs in the hands of well-informed and capable men, at sufficient salaries, with adequate staffs, wholly free from the caprice or ignorance of politicians. As such matters are almost wholly neglected in most parts of the country, it should be possible to follow from the beginning a well-trying plan, such as was demonstrated practicable by our government in Panama, as well as in other places. Seeing how badly conducted are many public services, and how much harm could befall the country if the management of sanitation were as faulty as some other branches, we can only hope that a higher standard will be set before we embark on any new hygienic efforts.

The difficulty of making the public realize the economy of prevention of disease has in the past been the chief reason for general neglect of hygienic efforts, and for imperfect work in almost all parts of the country. We were not accustomed to consider the cost of foes like infection and filth, and the cost of sanitary officers, detention hospitals and compulsory care of dangerous invalids. In the last three years we have, almost without a murmur of protest, paid many times the former taxes in order to retain our moral and political freedom, and we all know that the price, extravagance included, was justified. To state it in another way: We spent many times more to kill or even disable, as by gas, a single enemy soldier, than we spend to keep our own population free from communicable disease; just as we spent many times more to maintain roads for ammunition than we ever have to facilitate bringing farm products to cities, or to get the country doctor to his patients. For the cost of a battleship we could eradicate malaria and typhoid fever from many localities where they still flourish. For sums that to a secretary of war would seem trifling, we could make it possible for every tuberculosis patient to get necessary treatment in any stage of the disease. For the price of a single battle we could see to the health of every schoolchild, and train all those in schools and colleges in proper hygienic lines. The cost of sanitation of work places would be a bagatelle. Of course, this could not be done under the old pork-barrel method of administration, or even according to the methods used in some lines, like aviation, in the war. But with a corps of experts, that could be formed now better than ever before, and a fund properly budgeted and honestly administered, a better return could be made than on any money ever spent by the country.

TRADE UNIONS AND MEDICINE

For a long time now the medical profession of the United States has been spoken of by some of its critics as a trade union. To be sure it has never adopted any of the methods so characteristic of trade unions in its relation to the rest of the population; and although it has had, for nearly twenty years, a very efficient organization, it has never used its power for any other purpose than some public welfare, and in particular has not attempted to gain financially or politically, either for the organization or for individuals. Under the circumstances it seems that the use of the term reflects as much on the trade unions as on the medical profession.

But the trade union movement is making rapid accretions, and in spite of the short-sightedness of

many leaders of American labor, should be given every opportunity for proper expansion. Teachers in schools and universities have formed unions. From the experience of other countries we may find pressure on physicians also to unionize. Before we do this we should remember that we are not merely craftsmen; we occupy a position comparable rather to that of policemen, firemen or soldiers. Any such allegiance as those exhibited even by the most conservative unions would be wholly at variance with our duties, as understood at all times and in all places by physicians.

When we see, especially, the harm that can be done by unscrupulous, dishonest or overambitious representatives of unions—harm not only to innocent fellow citizens, but to trade unionism itself—we can draw a lesson regarding one danger. There are others. Trade unions too often consider wages the main thing, the quality and quantity of work quite secondary. One can see a danger from this tendency, which may last longer than either the capitalistic or the feudal systems, in the case of teachers' unions. Few teachers are paid enough, but many are paid more than they earn. In the agitation for increased appropriations, I have not seen any recognition of this fact, nor any intention of requiring a higher standard of performance when salaries are made fairly commensurate with comfort. The same danger would threaten if physicians had unions. How rarely in any unionized trade does one see pride in a neat job, or any effort to get it. The controller is keen to detect any detail that might be the sole function of another union, and fines a plasterer, for example, if he knocks in a protruding nail with the handle of his trowel; but both workman and helper may loaf to their heart's content without remonstrance. So let us keep out of unions as long as we can, and if we are forced into them as a result of social evolution, let us try to retain our pride in a good job and remember that ours is a calling in which there is work to do all the time; and time for our own comfort must often be negligible.

But there is already a class struggle going on, and as usual at such a time, it is all the more dangerous because declarations of war have either not been formally made, or if so, they have been concealed by those who fear to face the verdict of contemporaries or posterity. The coal strike is an example of a new method of trades union struggle. Incidentally, it illustrates the mental inertness of the people. As soon as the government took its stand even the most judicious newspapers assumed that the strike was over, though even now the coal situation grows more serious. One is reminded of the courtiers who assured King Canute that the waves receded at the royal command. It would have been better to imitate those, who, when hungry and unable to fill their stomachs, obliterate the void by tightening their belts.

PHYSICIANS AS SERVERS OF HUMANITY

What stand should physicians take in this war? Having the highest example, one can decide without trying to go into the merits of the case. I should say physicians should take the same stand they all took in 1914, and some even after that time, in international war. They should serve humanity wherever possible. But this, of course, is when they act as individuals, so that, to take a very concrete example, in case of a strike affecting the lives and health of the community, as of miners, railroad hands or dealers in food, they should apply the counterstrike, as members of cor-

porate bodies. If a hospital cannot get coal or food, then no one in the unions concerned should be admitted to the care of such a hospital. To do other than this would be a crime against the helpless, though the individual physician would be free to exercise his care wherever he could, and should help even those who call themselves his class enemies, when they are sick or wounded.

To do this may seem to require more charity than the twentieth century can afford. I do not think so. Let us hope, however, that instead of having to devote our talents to such work, we may soon enter another era, in which the only strife will be that for excellence. *Punch* not long since had a cartoon in which a great politician was posed as Hamlet, and quoting the bitter lines: "The time is out of joint;—O, cursed spite, that ever I was born to set it right!" This was a reflection of the soul of Hamlet, but other sentiments are more in keeping with the present time.

Class struggles of the most brutal kinds are not new. From time to time the so-called peasant wars sprang up as an expression of injustice, but the greatest insurrection before our time, the French Revolution, showed that after the main object was achieved communism and anarchy were not really profitable. Some centuries ago, the robber barons of Hohenzollern used to pillage their proletarian or bourgeois neighbors, and later successfully despoiled their neighbor princes, kings and emperors. No one now cares where they are. Their successful days seemed long and were in fact too long; but even if the present chaotic times last as long as the period of divine right of kings, it will be short as compared with biologic processes.

We have seen the dream of the Victorian poet realized in its most impossible part—we have seen the "airy navies grappling in the central blue." Why not hope that some other parts will be realized, that the war drums will throb no longer.

EFFECTS OF TYPHOID FEVER AND TYPHOID VACCINE ON PUL- MONARY TUBERCULOSIS*

E. E. CLOVIS, M.D.

AND

G. E. MILLS, M.D.

TERRA ALTA, W. VA.

Many of the older physicians and writers viewed the coexistence of pulmonary tuberculosis and typhoid fever as offering a grave prognosis; and as there are undoubtedly a large number of physicians who at present have the same views, a report of our experience gained during an epidemic of typhoid fever at this institution during the months of August and September, 1919, should be of value. That the diseases may coexist has been recognized for a long time; and unquestionably, it not infrequently occurs in private practice, unknown in the majority of instances to the physician, as the patient may have a healed tuberculous lesion of which he is often unaware. It is well known that the symptoms of one disease may closely resemble those of the other, as miliary tuberculosis is often mistaken for typhoid fever, and as pulmonary tuberculosis may begin with symptoms that may simulate the features suggestive of typhoid fever.

* From the State Tuberculosis Sanatorium.

No doubt this complication has occurred in several sanatoriums; but the available literature reveals only one reported epidemic,¹ which took place in the summer of 1917 at Trudeau Sanatorium, Saranac Lake, N. Y. Altogether there were fifteen cases in that series, eleven of which were being treated for pulmonary tuberculosis. The disease proved fatal with two of the patients who had had active tuberculosis prior to the typhoid infection, while the third active case showed no more advancement of pulmonary lesion than otherwise would have occurred. Of the remaining eight, the general condition of three remained unchanged, while in five it was improved.

There were sixteen persons infected during the epidemic at this institution, nine of whom were patients, and two former patients, who were employed as storekeeper and orderly, a foreman of construction, three laborers and a maid. As five of these were outside employees and were nontuberculous, they shall not be considered in this report.

HISTORY OF EPIDEMIC

CASE 1.—Aug. 4, 1919, a patient, D. C. B., who for several weeks had had a low grade temperature, developed a higher temperature than usual.

CASE 2.—One day later, August 5, a patient, F. C. M., who a month before had had an exacerbation of symptoms, had a chill followed by high temperature. This and the preceding patient were at first thought to have developed an acute tuberculosis.

CASE 3.—On the same day, August 5, a patient, I. Q., who had had a previous malaise, also vomited and had a slight rise in temperature.

CASE 4.—August 9, a patient, H. W., had a severe chill, followed by a high temperature. He had a complication of pulmonary tuberculosis and bronchiectasis, and not infrequently, when the lungs did not drain properly, had chills followed by fever.

CASE 5.—One day later, August 10, a patient, J. N. T., vomited and had a high temperature.

CASE 6.—On the same day, August 10, a patient, L. L., had a rise of temperature following a malaise of several days' duration.

CASE 7.—Four days later, August 14, T. D. M., a hospital patient who was having a temperature range of from 97 to 100.4, developed a higher temperature.

CASE 8.—On the same day, August 14, the storekeeper, D. N. R., whose pulmonary lesion was quiescent, had a rise of temperature.

CASE 9.—At the same time, August 14, a patient, S. H. H., who had been having a temperature range between 97.6 and 99.4, developed a higher temperature.

CASE 10.—August 20, L. J. H., a patient, had a moderate rise of temperature.

CASE 11.—Six days later, August 26, R. I. V., an orderly, who had had no contact with the former patients, developed a high temperature.

SOURCE OF INFECTION

Immediately after tentative diagnosis of typhoid fever was made, samples of milk, drinking water, ice, and water from a nearby spring, from which some of the patients had been drinking, were examined to determine the source of infection.

The supply of ice was obtained from a factory, the milk from our own dairy, and drinking water from springs on the mountain side, which at that time were very low, and from the spring to which reference has

been made. This spring was located below and to the east of the hospital, and had been in use for several years. As two of the laborers who drank from the spring and not from the water supply in the buildings became ill of typhoid, the spring was at once suspected.

In the meantime the report of the bacteriologist was to the effect that all samples were in excellent condition except water from the spring, which showed the presence of *B. coli*.

This led to an investigation of our sewerage system. The main sewer was located to the south and across a ravine from the spring, but the sewer leading from the north wing of the hospital was located about 50 yards above and was supposed to be cemented and water tight. This part of the system was found to be almost completely obstructed and was opened with great difficulty, indicating that it had been in this condition for some time. On questioning those who had been drinking from this spring, we learned that a peculiar taste—that of creosote—had been noticed in the water for several days, and with one exception, all typhoid patients had been occasionally drinking this water. As we were using a creosote disinfectant in our lavatories in the hospital, it was sufficient proof that our sewage had contaminated the spring and that it was the source of our epidemic. As there were many changes made among the patients on the north wards of the hospital, we were unable to make a thorough investigation for the carrier.

REVIEW OF PATIENTS' PULMONARY TUBERCULOSIS AND TYPHOID FEVER

CASE 1.—D. C. B. (No. 1144), admitted May 8, 1919.

Tuberculosis.—Examination on admission: Chest: Marked dullness to fourth rib, both upper lobes, and to apex of base in back. Râles fairly active apex to base, and to lower angle of scapula back. Râles without cough. Condition far advanced. Sputum, positive. Diazoreaction negative. Temperature, from 98 to 99.4. Patient was substandard, and condition was slowly progressing at the time of the typhoid. Temperature, from 98 to 100. Sputum was positive prior to infection.

Typhoid.—Onset, August 4. Epistaxis. Widal test, positive. Diazoreaction, positive. Few rose spots. Delirium at intervals. Highest temperature, 105. On thirty-seventh day, relapse. Spleen palpable 2 inches below costal margin. Temperature returned to usual level on sixty-fourth day. Severe infection.

CASE 2.—F. C. M. (No. 1140), admitted, May 8, 1919.

Tuberculosis.—Examination on admission: Chest: Right, moderate dullness to fourth rib. Left, slight dullness, apex to third rib; thickened pleura with flatness left base. Right, râles on cough apex to fourth rib. Left, râles, apex to base without cough. Breath sounds very weak at left base. Condition far advanced. Sputum, positive. Diazoreaction, negative. Temperature, from 99.8 to 102.4. Patient was admitted to the hospital, where he remained until June 11. Transferred to cottage and continued to have occasional temperature from 99.2 to 99.4. Condition was slowly progressing at time of typhoid illness. Sputum persisted positive.

Typhoid.—Onset, August 5. Epistaxis. Two severe chills. Widal test, negative (only one examination). Diazoreaction, positive. Delirium at intervals for three days. Highest temperature, 104.4. Severe infection. On forty-eighth day, September 21, moved to his home. Temperature range at time of discharge, from 98 to 102. Two months later, in reply to inquiry, patient stated that his temperature had returned to the usual level and that other symptoms were practically the same as before typhoid.

CASE 3.—I. Q. (No. 1201), admitted, July 15, 1919.

Tuberculosis.—Examination on admission: Chest: Right, slight dullness at apex. Left, slight dullness to second rib.

1. Brown, Lawrason; Heise, F. H.; Petroff, S. A., and Wilson, G. E.: A Study of Effects of Typhoid and Antityphoid Immunization on Pulmonary Tuberculosis, *Am. Rev. Tuberc.* 11:717 (Feb.) 1919.

Left, râles on cough to second rib; expiration prolonged at both apexes. Condition, incipient. Sputum, negative. Diazo-reaction, negative. Temperature, normal. Patient had made slight improvement in general condition prior to typhoid infection. Sputum persisted negative.

Typhoid.—Onset, August 5. Severe vomiting. Widal test, positive. Diazo-reaction, positive. Highest temperature, 103.2. Temperature fell to normal on thirtieth day. Moderately severe infection.

CASE 4.—H. W. (No. 1113), admitted, April 1, 1919.

Tuberculosis.—Examination on admission: Chest: Right, marked dulness to fifth rib. Left, slight dulness at apex. Right, râles without cough, apex to base. Left, râles on cough, apex to base front, and to lower angle of scapula back. Condition, far advanced pulmonary tuberculosis and bronchiectasis. Sputum, negative. Diazo-reaction, negative. Temperature, normal. Patient had occasional exacerbations with chills and rise of temperature, but general condition had shown slight improvement at time of his typhoid illness. Sputum had persisted negative.

Typhoid.—Onset, August 9. Widal test, positive. Diazo-reaction, positive. During first three weeks of illness had nine pulmonary hemorrhages, averaging 2 ounces. Highest temperature, 104.4. Temperature returned to normal thirty-seventh day. Severe infection.

CASE 5.—J. N. T. (No. 1047), admitted June 6, 1913.

Tuberculosis.—Readmitted, Nov. 18, 1918. Examination on admission: Chest: Right, marked dulness to fourth rib. Left, slight dulness to second. Right, râles to fourth rib on cough and to lower border of scapula. Left, râles on cough to second rib. Condition, moderately advanced. Sputum, positive. Diazo-reaction, negative. Temperature, from 98 to 100. Patient was admitted to hospital, and after prolonged rest was moved to cottage. Discharged, June, 1916, as quiescent. November, 1918, was readmitted to hospital. Had severe hemoptysis. Improved and was moved to cottage in June, where he had onset of typhoid infection. Sputum persisted positive.

Typhoid.—Onset, August 10. Profuse epistaxis. Widal test, positive. Diazo-reaction, positive. Few rose spots. Spleen, palpable under costal margin. Had two attacks of hemoptysis, following which, both lungs became congested. Delirium for three days and at intervals for two more. Small amount of blood in involuntary stool on twentieth day. Highest temperature, 105. Temperature returned to normal on thirty-ninth day. Severe infection.

CASE 6.—L. L. (No. 1216), admitted, July 31, 1919.

Tuberculosis.—Examination on admission: Chest: Right, slight dulness to second rib. Left, slight dulness at apex. Right, râles on cough at second rib. Left, râles on cough at apex. Condition, incipient. Sputum, positive. Diazo-reaction, negative. Temperature, normal. Patient's general condition had slightly improved at time of typhoid illness. Sputum persisted positive.

Typhoid.—Onset, August 15. Widal test, positive. Diazo-reaction, positive. Palpable spleen. Delirium for twenty-four hours. Highest temperature, 105. Temperature returned to normal on thirty-fourth day. Severe infection.

CASE 7.—T. D. M. (No. 951), admitted, June 4, 1918.

Tuberculosis.—Examination on admission: Chest: Right, moderate dulness to third rib. Left, slight dulness at apex. Right, râles on cough to fourth rib and to lower third of scapula in back. Left, râles at apex. Condition moderately advanced. Sputum, positive. Diazo-reaction, negative. Temperature, normal. Patient had severe hemoptysis in September, 1918, followed by a marked extension of lesion with cavitation in right upper lobe, and since this exacerbation his pulmonary condition has been slowly progressing. Temperature, from 97 to 100.4, and sputum positive, prior to typhoid illness.

Typhoid.—Onset, August 14. Widal test, positive. Diazo-reaction, positive. Palpable spleen. Highest temperature, 103. Temperature down to usual level, thirty-ninth day. Moderately severe infection.

CASE 8.—D. N. R., admitted, Sept. 29, 1914.

Tuberculosis.—Examination on admission: Chest: Right, marked dulness to fourth rib. Left, slight dulness at apex. Right, râles apex to base front; apex to lower border of scapula back. Râles on cough. Left, râles on cough to third rib. Condition far advanced. Sputum, positive. Diazo-reaction, negative. Temperature, 100 plus. Patient improved and was discharged as quiescent, in June, 1916. Employed as store-keeper at time of typhoid fever. Sputum persisted as positive.

Typhoid.—Onset, August 14. Widal test, positive. Diazo-reaction, positive. Highest temperature, 102.4. Temperature fell to normal, thirtieth day. Mild infection.

CASE 9.—S. H. H. (No. 1072), admitted, Feb. 7, 1919.

Tuberculosis.—Examination on admission: Chest: Right, slight dulness at apex. Left, moderate dulness to third rib. Right, râles to second rib. Left, râles to fourth rib. Râles only on cough. Condition moderately advanced. Sputum, positive. Diazo-reaction, negative. Temperature, from 97 to 99. Patient's pulmonary condition had slightly progressed at time of typhoid fever. Sputum persisted positive. Temperature, from 97.6 to 99.4.

Typhoid.—Onset, August 14. Widal test, positive. Diazo-reaction, negative. Highest temperature, 101.4. Patient had typhoid fever in childhood. Temperature returned to normal on twenty-third day. Mild infection.

CASE 10.—L. J. H. (No. 1153), admitted, May 21, 1919.

Tuberculosis.—Examination on admission: Chest: Right, moderate dulness to third rib. Left, moderate dulness to third rib. Râles, apex to base both lungs and middle scapula back. Râles mostly without cough. Condition far advanced. Sputum, positive. Diazo-reaction, negative. Temperature, normal. Pulmonary condition had shown slight improvement, and general condition was very much improved before onset of typhoid fever. Sputum persisted positive.

Typhoid.—Onset, August 20. Widal test, positive. Diazo-reaction, positive. Before onset, patient was given one injection of typhoid vaccine. Highest temperature, 103. Temperature returned to normal on fifteenth day. Mild infection.

CASE 11.—R. I. V., admitted, April 9, 1917.

Tuberculosis.—Examination on admission: Chest: Right, slight dulness to third rib; moderate dulness at base, and râles on cough to fourth rib, without cough at base. Condition moderately advanced. Sputum, negative. Diazo-reaction, negative. Temperature, normal. Patient discharged in November, 1918, with case apparently arrested. Employed as orderly at time of typhoid illness.

Typhoid.—Onset, August 21. Widal test, positive. Diazo-reaction, positive. Two injections of typhoid vaccine had been given prior to illness. Highest temperature, 104.2. Temperature became normal, twenty-seventh day. Seven days later a rise to 100.2 was noted. Thrombosis of left femoral vein. Temperature returned to normal on fortieth day. Severe infection.

TREATMENT OF PATIENTS

General Measures.—The typhoid patients were removed to the hospital and placed in well ventilated and screened rooms, and when their condition permitted, the beds were pulled out into an open ward and were covered with gauze netting. It is hardly necessary to state that the patients were requested to change the position in bed sufficiently often to prevent the occurrence of congestion and the development of bed-sores.

Prophylaxis.—Strict measures were exercised in proper disinfection of dishes, bedclothing, sputum, urine and feces. All attendants were carefully instructed in the proper use of disinfectants.

Diet.—The high caloric feeding of Coleman was deemed advisable. In Table 1 an example is given of a day's menu with nourishments:

Substitutes of grape juice, baked potatoes, jello, bouillon, buttermilk and malted milk were given from

time to time. Four of the patients were so toxic for a few days that they were unable to take more than 1,500 calories in twenty-four hours; but as soon as possible they were increased to the daily average of 3,500.

Medicinal.—Five grains of salol were given every six hours. Ten drops of dilute hydrochloric acid were given three times a day after eating. Two drams each of aromatic cascara sagrada and glycerin were given every other night, alternating with a soapsuds enema.

Hydrotherapy.—A tepid sponge bath was given three times a day followed by an alcohol rub. A cold sponge was given only when there was manifestation of nervous symptoms or extremely high temperature.

Convalescence.—Protracted bed rest was deemed essential in all the cases. Those whose pulmonary condition was quiescent prior to illness were kept at rest two weeks before they were permitted to sit up, and those with active trouble were kept at rest for a week longer. During this period, calories were increased and solid food was given as soon as possible in the individual case.

THE EFFECT OF TYPHOID FEVER ON PULMONARY TUBERCULOSIS

The conclusion of the effects on pulmonary tuberculosis in our series of eleven cases was made two months following convalescence. Of this number, four were classed as active with abnormal temperature prior to the typhoid infection, and all were far advanced.

TABLE 1.—MENU FOR A DAY

BREAKFAST			Calories
Oatmeal gruel	5 oz.		167
Egg	1		80
Milk toast	1 slice (milk, 3 oz.)		164
Butter	10 gm.		75
Cream	2 oz.		120
Coffee			
Sugar (granulated)	5 gm.		60
NOURISHMENT, 10 A. M.			
Egg-nog	7 oz.		220
Total			886
DINNER			
Cream of potato soup	8 oz.		200
Milk toast	1 slice (milk, 3 oz.)		164
Custard	4 oz.		262
Milk	7 oz.		150
Coffee			
Sugar (granulated)	5 gm.		60
NOURISHMENT, 3 P. M.			
Lactose ice cream	4 oz.		390
Total			1,226
SUPPER			
Beef juice	6 oz.		46
Egg	1		80
Milk toast	1 slice (milk, 3 oz.)		164
Mashed potatoes	50 gm.		41
Cocoa	6 oz.		197
NOURISHMENT, 10 P. M.			
Lactose lemonade	6 oz.		360
NOURISHMENT, 1 A. M.			
Milk	7 oz.		150
NOURISHMENT, 4 A. M.			
Lactose orange albumin	6 oz.		390
Total			1,428
Total for 24 hours			3,540

Two of the four cases have continued to advance, and judging from a report received, the condition of the patient who had returned home has also advanced but in no case more rapidly than before the onset of typhoid. The remaining patient has shown a slight improvement in general condition.

Three of the total cases were classed as active without rise of temperature but with other symptoms, as cough, streaked sputum and pleurisy. Two of these patients have shown improvement in their general condition, while the condition of the other is unchanged.

Three of the remaining four cases were classed as quiescent, and the other as apparently arrested. Two of these patients have shown improvement in both pulmonary and general condition. One has shown improvement in general condition, while there is no appreciable change in the condition of the other.

With one exception, the patients were weighed as soon as they were able to be weighed, and it was found that eight had lost from 5 to 12 pounds and that one had actually gained 5 pounds, while the weight of the other remained the same.

EFFECTS OF TYPHOID VACCINE ON PULMONARY TUBERCULOSIS

In all, sixty-two patients were given three injections of typhobacterin. The initial dose consisted of 500 million bacilli, and the second and third 1,000 million

TABLE 2.—REACTION OF TUBERCULOUS PATIENTS TO TYPHOID VACCINE

	No. Reaction		Mild Reaction		Moderate Reaction		Severe Reaction	
	No.	Per Cent.	No.	Per Cent.	No.	Per Cent.	No.	Per Cent.
Active	15	41	9	24	8	22	5	13
Inactive	13	52	8	32	4	16		
Total	28	45	17	27.5	12	19.5	5	8

each. The injections were given ten days apart, and the patients, who were on exercise, were requested to remain quiet for forty-eight hours. None were given vaccine if they were having abnormal temperature, or if there was a recent hemorrhage or streaked sputum. Of the total cases, nine were incipient, twenty-four moderately advanced, and twenty-nine far advanced. Of these, thirty-seven were classed as active, and twenty-five as inactive. A reaction was regarded as mild when there was a slight aching, malaise or pleurisy, or if the temperature did not exceed 100; as moderate when the temperature did not go above 101, and as severe when the temperature exceeded 101.

It is interesting to note that a higher percentage of the inactive cases gave a mild reaction than the active cases. As was expected, the active cases gave a higher percentage of moderate and severe reactions than the inactive. The results obtained in our series of sixty-two cases are given in Table 2.

SUMMARY AND CONCLUSIONS

1. The coexistence of these diseases should require a high caloric feeding.
2. Prolonged bed rest during convalescence is advisable as a precautionary measure.
3. Typhoid vaccine gave severe reactions only in the active cases, but with no permanent bad effects.
4. Patients with inactive pulmonary tuberculosis may have typhoid fever without any detrimental effects on the pulmonary condition, while the general condition may often be benefited.
5. Patients with active pulmonary tuberculosis may have typhoid fever and recover without a more rapid advance in the pulmonary condition than would have occurred had they not had typhoid.
6. Pulmonary tuberculosis did not have any appreciable effect on the course of typhoid fever.

Health First Means Safety First.—When all employers realize that medical inspection of employees is quite as important as regular inspection of the machinery itself, we can look hopefully for a great reduction in the amount of accidents.—*Minnesota Health J.*, Nov. 20, 1919.

AN IMPROVED TEST FOR THE DETECTION OF GLUCOSE, ESPECIALLY IN URINE

WALTER S. HAINES, M.D.

GILBERT P. POND, M.D.

AND

RALPH W. WEBSTER, M.D., PH.D.

CHICAGO

Some years ago one of us (Haines¹) introduced a test for sugar in the urine which has found wide acceptance by the profession. The solution suggested at that time contained copper sulphate, potassium hydroxid, glycerin and water in these proportions:

Copper sulphate	30	grains
Potassium hydroxid	1½	drams
Glycerin	2	fluidrams
Water	6	fluidounces

These proportions have been more or less changed by different investigators and transformed into the metric system. The method, used with this test solution, is generally known and consists in heating to boiling about 5 c.c. of the test solution and adding from 8 to 10 drops of the suspected sample of urine. If sugar is present, a brick-red cloud is formed which eventually settles to the bottom of the tube. This solution, if made with pure ingredients, keeps indefinitely and has been found to be relatively delicate and quite reliable.

It occurred to us that the original solution might be improved on in such a way as to increase its delicacy and also to permit of the performance of the sugar test by the ring or contact method. The modifications introduced by us enable one to detect with certainty amounts above 0.03 per cent. of sugar, which is about the upper limit of the so-called "normal" sugar of the urine. In other words, the delicacy of the test is increased so that sugar in pathologic amount will be indicated, but physiologic sugar will not be shown. While this test is not as delicate as the special solutions of Folin² and of Benedict and Osterberg,³ yet this new Haines solution has the advantage over the latter solutions that it will show sugar only in pathologic amounts, while the other solutions mentioned will show sugar in practically every specimen of urine examined. It is, therefore, a clinical test in contradistinction to the others, which are too delicate for such purposes.

Owing to the increase of the specific gravity of the solution, by the addition of the larger amount of glycerin, the employment of the contact test becomes a matter of the greatest simplicity. However, one precaution must be taken before this test may be applied: Owing to the fact that the phosphates of the urine precipitate, when added to the alkaline copper solution, these interfering substances must be removed before the contact test shows in its most perfect manner; otherwise a confusing contact ring is observed, which might lead to possible errors in interpretation. This removal is accomplished by adding to the urine in a test tube 5 or 6 drops of a 5 or 10 per cent. solution of sodium or potassium hydroxid (or the official liquor potassii hydroxydi may be used), and allowing the phosphates

to settle out or centrifuging or filtering if desired to hasten the process. For coarser clinical purposes the test may be used with urine from which the earthy phosphates have not been precipitated, and we have occasionally employed it in this way. If the sugar present is 0.1 per cent. or upward, the reaction with the untreated urine usually comes out quite unequivocally; but, if the amount of sugar is below 0.1 per cent., the removal of the phosphates is essential to obtain entirely reliable results. It was thought that this precipitation of phosphates at the point of contact could be averted by the addition of sodium citrate or Rochelle salt to the copper solution, but this was found to be ineffective, as the ring appeared, although slightly slower, even when as large amounts as 30 gm. of either of these salts were added to 100 c.c. of the copper solution.

The composition of the improved Haines solution is:

Copper sulphate	5	gm.
Glycerin	250	c.c.
Potassium hydroxid ⁴	20	gm.
Distilled water to	1,000	c.c.

The copper sulphate is dissolved in a mixture of the glycerin, and an equal amount of water, with the aid of gentle heat. The potassium hydroxid should be dissolved in about 200 c.c. of water and added to the copper solution with constant stirring, the whole being made up to volume with distilled water. This solution keeps indefinitely, although with many of the specimens of glycerin now obtainable on the market a reduction may be observed. If, however, the solution be allowed to stand in a warm place for forty-eight hours, the clear supernatant fluid may be decanted or filtered from the precipitated cuprous oxid, without impairing its delicacy.

This solution may be used in the same manner as directed for the original Haines solution, but a much more delicate and beautiful reaction is obtained as follows: Heat about 5 c.c. of the copper solution to boiling in a test tube, remove from the flame, and hold at an angle of from 30 to 40 degrees. To this add, by means of a medicine dropper, from 10 to 20 drops of the urine, freed from phosphates as outlined above, in such a manner that a distinct zone of contact is formed between the copper solution and the urine. The tube is then placed in an upright position and the reaction noted. If sugar is present in quantities exceeding 0.1 per cent., a brick-red or yellowish ring will immediately appear at the junction of the two liquids. If the amount of sugar is less than 0.1 per cent. ranging down to 0.03 per cent., the ring will appear in from a few seconds to slightly less than a minute, the smaller quantities showing slower reactions with a tendency to a more yellowish color of the ring. In urines containing no pathologic sugar, no ring of any kind will be noted at the zone of contact.

In order to determine whether this new Haines solution offered any advantage, in the performance of a contact test, over other qualitative sugar test solutions, comparisons were made with the solutions of Benedict⁵ and of Folin and McEllroy.⁶ With the solution of Benedict, using the phosphate-free urine, a slight white contact ring was formed with normal urines, and with sugar-containing urine no distinct ring, indicative of sugar, was observed until the solution had stood for considerably longer than was neces-

1. Haines, W. S.: *Med. Examiner* 15: 569 (Dec. 1) 1874.

2. Folin, Otto: *J. Biol. Chem.* 22: 327, 1915.

3. Benedict, S. R., and Osterberg, E.: *Determination of Sugar in Normal Urine*, *J. Biol. Chem.* 34: 195 (April) 1918.

4. Or 14.3 gm. of sodium hydroxid.

5. Benedict, S. R.: *J. Biol. Chem.* 5: 485, 1908-1909.

6. Folin, Otto, and McEllroy, D. S.: *J. Biol. Chem.* 33: 513 (March) 1918.

sary with the Haines solution. When the solution of Folin and McEllroy was used with phosphate-free urine, the contact ring in normal urines was so marked that it could not permit of the use of this contact test.

This improved Haines test has the following advantages:

1. The reaction is concentrated to a single plane, thus increasing its visibility.
2. Only one heating is necessary, and there is no long standing before the reaction appears.
3. It will demonstrate pathologic sugar in amounts greater than 0.03 per cent.
4. It differentiates between pathologic and physiologic sugar.
5. It gives a clear-cut, decisive result in a minimum of time.

TUBERCULOSIS

A CITY PLAN*

C. V. CRASTER, M.D.

NEWARK, N. J.

It may be said "tis not in mortals to command success," yet there may be some doubt in our minds whether in our past efforts to control tuberculosis we have quite deserved to succeed.

If we will look back fifty years into the history of medicine it will be clear that the clinical symptoms of tuberculosis, the case histories of the disease, and the pathology of the gray tubercles were intimately known. Austin Flint in America, and Trousseau in France had demonstrated the relationship between tuberculosis and the lack of fresh air and sunshine, sedentary occupations, and those conditions that are the result of careless and unclean habits found in congested areas of population. Furthermore, the infectivity of the human tuberculous lesion had been suggested by Villemin's experiments with guinea-pigs in 1865. Aitken, writing at this period, said, "The stabled cow, the rabbit, the monkey, the caged lion, tiger or elephant, are almost invariably cut off by tuberculosis affections."

Koch's brilliant discovery of the causative organism in 1882 served to place the seal of certainty on the theory of infectivity, but did not add to our knowledge as to the paths of infection or the manner in which infection might be conveyed.

A review of the yearly mortality from tuberculosis will show that throughout the civilized world there has been reported year after year a continuous decrease. The picture, however, is not comparable in extent with that seen in the number of deaths from epidemic diseases in general; the curve of decline is less abrupt, the grade gentle and in sharp contrast to that seen in scarlet fever, diphtheria, typhoid fever or in smallpox.

It may be said that in spite of the great decreases recorded in the mortality from tuberculosis in the registration area, the disease must be still prevalent to a degree resembling the widespread epidemics of contagion of earlier days. In spite of intimate knowledge, it is evident that our empiric methods have so far failed. Tuberculosis, "lingering like an unloved guest," by its very perversity calls for our utmost efforts for its eradication.

The draft examinations are too recent for us to forget the 82,000 young men who were reported as unfit

for national service on account of tuberculosis. The experiments at Framingham have demonstrated that at least 2 per cent. of an average industrial community would be found after examination to be suffering from tuberculosis in some form or other, and they have left an increasing feeling that we are as yet ill informed as to the physical standing of communities. In the country at large it is estimated by the National Industrial Conference Board that 1 per cent. of the total population is tuberculous.

In looking at these enormous figures it is evident that the control of tuberculosis is still far from what it should be in the present state of our knowledge. Tuberculosis has been regarded as a disease that is the result of hereditary inclinations, and then again as a disease of a contagious and communicable nature; nevertheless there has been no decided decrease in the mortality figures. If tuberculosis were a communicable disease whose clinical symptoms were easily discoverable, the problem of control would be simple. It is more than this, however, for like the venereal disease it presents the twofold aspect of a communicable disease and a social problem so important as to require a complete readjustment of our views on the subject.

There is a factor in its persistence that has somehow escaped our notice. It may well be that this is the neglect of the social side, and that it is responsible for our failure to bring about good results that are more permanent in tuberculosis control. Support of this view is found in the acknowledged experience that the onset of the disease is largely dependent on unusual habits and manners of living which subsequently react in physical susceptibility. Probably too much emphasis has been placed on the contagious disease aspect and too little on the predisposing causes. The social factor is also strong in determining the opportunity for early advice and treatment. Society makes as yet no provision for sick pay, either for the patient or for the dependent family.

Tuberculosis will not persist when communities live right; when fresh air is regarded as a vital necessity, and when methods of living depart least from accepted standards of health. On the other hand, in this country there may be certain national and climatic conditions which bring about a susceptibility to tuberculosis. Our severe winters are probably responsible in part for the depressing influence of overheated dwellings. The craze for up-to-date bathrooms and plumbing may well have brought about the greater danger of the common wash basin. The old-fashioned ewer and basin in each bedroom, although inconvenient, certainly provided the more sanitary equipment for the home.

In outlining a city plan for tuberculosis control, modifications will be found necessary to meet local conditions. Any occupation or community life in which conditions are apparently predisposing toward tuberculosis will require special handling.

The city plan may be divided into certain definite lines of activity, as outlined in the accompanying tabulation. None of these separately can be considered more important than the others; the success of the whole will depend on the acceptance of the value of each.

CONTROL OF INFECTION

Reporting by Physicians.—In the control of infection it will be agreed that it is vitally important to know where the disease exists, for without this knowledge no supervision is possible. There is some doubt, how-

* Read before the New Jersey Anti-Tuberculosis Association, Paterson, N. J., Nov. 8, 1919.

ever, as to what shall constitute a good standard of reporting excellence.

If we accept the dictum that there are twelve persons with tuberculosis for every recorded death from the disease, a city with an annual total of 100 deaths from tuberculosis has probably 1,200 persons afflicted with the disease in various stages. The average duration of life of the tuberculous person is difficult to estimate since there are so many variations in bodily resistance to the progress of infection. If the average duration of life in a purely empiric way is stated as three years, then a city with this number of deaths should have about 450 reported cases annually.

If the number of reported cases in any community is three times as large as the number of deaths from tuberculosis, we probably have a fair measure of notification by physicians. In checking up the reporting of cases, much information is obtainable by comparing deaths with report files. Duplicate reports of cases by one or more physicians should be accepted and paid for. The physician has no means of telling whether his patient has been reported previously. Similarly a follow up system of all sputum examinations made by municipal laboratories affords much information as to

accurate reporting. In this respect a policy of wise toleration that does not degenerate into the actual condoning of violations of the reporting law will prove an incentive to efficient reporting by physicians.

Nurses.—The services of the health nurse are too widely appreciated to require more than a brief comment. The importance of her work in the control of infection cannot be overestimated. The widest measure of success with the public depends as ever on the possession of tact and judgment, backed up by special training. I do not believe that a health nurse can give efficient service in a department unless her lines of action are specialized. An old adage still holds true: "Jack of all trades, master of none." It is only by special qualities of training and intelligence that a supervision of the tuberculous patient is possible which, apparently unobserved by the law abiding patient, is still there when occasion demands more drastic methods. The visiting nurse requires for the salvation of her patient the freest possible hand. Impossible tasks, such as the care of many patients, should not be attempted. It has been our experience in Newark that the best work is obtained when no more than 100 cases are assigned to each nurse. This number will generally bring about

a fair return of intelligent interest in the patients, provided distances are not excessive.

When the number of nurses is limited and the patients requiring supervision are many, areas of greatest prevalence may be selected for intensive work. In any case, interest tends to be lost when patients are many and the distances between visits are great. Let me state here that the work of the tuberculosis nurse is a health function. Only under a municipal board of health can the best results be attained in obtaining the necessary cooperation with municipal departments, with hospitals and other social agencies.

Clinics.—Activities against tuberculosis must radiate from the dispensary clinic as a center. Dispensaries are not always located in ideal neighborhoods. If a choice is possible, areas where tuberculosis is most prevalent should be selected. It must not be forgotten that a long trolley ride to a dispensary will seriously dampen the enthusiasm of the most optimistic nurses or patients. To the clinic come the ambulant patients not under private treatment, as well as all exposed children. An attractive feature for children is the provision of free milk or other food, such as biscuits. Milk for the purpose may be provided from what is left of milk samples taken by department milk inspectors. Little children are frequently reconciled to the discomforts of a physical examination if a glass of milk is held in one hand and a cracker in the other. Special efforts to attract mothers with children to the clinic are frequently successful if free transport to and from a clinic is provided. In Newark a special ambulance donated by the Red Cross performs wonderful work in this way.

In providing the free distribution of necessary sick appliances in dispensaries, extreme generosity with regard to sputum cups, towels and disinfectants is a good policy. Patients sometimes complain of the difficulty of obtaining metal sputum cups from medical supply houses. A number of these may well be stocked in the dispensary and sold to patients at cost.

Centralization of effort will result if the examinations for state and county sanatoriums can be made at the municipal clinic. Very definite efforts can also be made by means of illustrations and literature to influence patients to undergo hospital treatment. There has been some effort to discourage the term "tuberculosis clinics" and to substitute the term "health clinics." This is in line with the present day application of tuberculosis psychology, and may be employed without any loss of efficiency.

Where there are large colored communities, a special clinic is desirable. Colored physicians and nurses of a high type can be obtained with little trouble for the staffs of these clinics, and the results will repay the added outlay.

Hospitalization.—In Koch's original monograph he drew particular attention to the low tuberculosis mortality experienced in those European countries where hospital beds were provided in large numbers for tuberculosis sufferers. A similar experience has been noted in this country. Bonney says: "The evidence thus far presented is quite overwhelming to the effect that the closed institutions are everywhere responsible for a material diminution in the tuberculosis mortality rate among the neighboring inhabitants." Among the important efforts against tuberculosis is a campaign for an adequate number of sanatorium beds. Some beds should also be provided in local hospitals for emergency

bedridden patients waiting for admission to the county institution.

Boards of freeholders will seldom act to provide increased accommodations unless a popular demand for them is made very clear, backed by the opinion of the local boards of health. Such a campaign is necessary in every county in this state. That the present accommodation throughout New Jersey is inadequate is evident. More than half the counties of the state have no sanatorium at all for tuberculosis patients, and in only one, Union County, does the accommodation equal the minimum of one bed for each death from tuberculosis.

Before, however, sanatoriums can accomplish their function of healing every class of the community, a considerable change must take place in the attitude of the tuberculosis sufferers toward these institutions. The tuberculosis sanatorium is commonly regarded as the final step before dissolution instead of, as it should be, the first step toward recovery. For this public view the representative tuberculosis institutions are not to blame. The sanatorium must admit every suitable patient for treatment. It is no one's fault that patients have been largely recruited from the riffraff of the saloon, and the down and outs of public lodging houses, who are generally as hopeless in prognosis as they are in the finer feelings of respectability. It is unfortunate that public opinion has been allowed to look on our sanatoriums as institutions for incurables instead of places for recuperation and recovery.

It is desirable that institutional traditions in tuberculosis sanatoriums be reduced to a minimum. Freedom and homelike surroundings are synonymous: all that is needed is to cure temperamentally as well as physically. It is only in this manner that the person in the early stage of tuberculosis can be persuaded to take hospital treatment. As an indication of what should not be done, only recently a visitor to a well known sanatorium before being admitted to the ward was required to be swathed in a white robe, cap and respirator. What an unforgettable vision he must have been to the highly neurotic tuberculosis sufferer.

Day Camps.—It has been the experience of many communities that patients will attend day camps who refuse all other kinds of outdoor treatment. The attractive features are greater freedom, less restrictive rules, food and free medical advice. The patients can go and return home every night. Such a camp can be established on vacant land owned by the city, and purchased with city funds or bought by private subscription. These camps are not expensive, and they give satisfactory return for the expenditure. The tent colony carried out in some cities is equipped for all purposes, and includes dining hall, cooking tent and special accommodations for men and women. The attraction in this plan is its elasticity. Only enough tents need be erected to meet prevailing demands. The opportunities are for education in the personal care and prevention of infection, for medical treatment, and for vocational training. In Newark, tents bought by public subscription and presented to the department of health are lent to patients for use in back yards or adjacent lots. The plan works well, but requires careful selection of patients granted the privilege.

Laboratory Facilities.—The use made by physicians of laboratory facilities will depend very much on rapid and consistent service. The laboratory must be fed by a good system of culture stations, preferably located in drug stores where supplies of sputum boxes may be

obtained and where specimens may be left for collection.

Antispitting.—Spitting in public places should be regulated by an active propaganda. Public notices placed on road and traffic signs are effective reminders if sanitary inspectors are occasionally detailed on the streets to make arrests. The fine imposed for this offense should be a small one, the police proceedings being sufficiently deterrent in themselves. The fine in Newark is from \$2 to \$10. It is better to have a small fine collected than one so large that judges hesitate to impose it.

Milk Supervision.—It is contended that about 6 per cent. of all tuberculosis cases are of bovine origin. Where there is a raw milk supply, constant vigilance at the point of production is the only safeguard against tuberculosis. The tuberculin test of all cattle used for raw milk supplies must be insisted on. Careful watch on this type of dairy herd should be kept for plugged cattle and infected udders. The tuberculin test is usually required by municipalities annually, and it might well be made every six months. No new cattle should be allowed to be added to a herd before being tested. No local board of health should allow the sale of raw milk unless the supervision as outlined above is possible. The alternative is pasteurization of all milk supplies at the point of production.

SOCIAL PROGRESS AND RELIEF

There is no disease so closely connected with poverty and general distress as tuberculosis. All conditions found under these circumstances make for a more effective spread of infection. Intimate contact without regard to personal protection, filthy hands, food and china, and contaminated fingers are the supposed ways of spreading infection.

Much of the dirt, squalor and misery found in tenement life undoubtedly will favor infection with tuberculosis, but many of these unfortunates are themselves recruited from the ranks of the tuberculous. Improvement in the situation must come from every direction, and will be facilitated by an awakening of the people to the fact that clean habits and customs of living should be more a commonplace than an exception.

The pioneer work of the antituberculosis associations, national and state, in bringing the knowledge of the facts of tuberculosis to the public will always remain a wonderful tribute to patient and persistent effort. It is these associations alone that we must thank for the general recognition by the public of the gravity of the tuberculosis situation, as it is through their efforts that local boards of health have adopted more active methods to combat the disease. Where the tuberculosis association may well remain a valuable agency is in arranging plans for active public propaganda. There is much work for these associations to do along educational, social and economic lines. Their independence as citizen committees gives their efforts an appeal to public sympathy always timely and effective in results. What shall be done to relieve the poverty in tuberculosis is a question always demanding and receiving no satisfactory answer. Food, clothing and money for rent are constantly asked for, or at least obviously needed. These patients should not be poor and applicants for alms. Their poverty is due not to vicious habits, intemperance or crime, but to the effects of a disease which they surely would have been protected against if society had been properly organized. The tuberculosis victim can surely demand the

protection of the community, not in doles of charity but as sick pay, rightfully earned by labor for the community. How such a scheme of assistance should be carried out is still a matter of conjecture. Many authorities are in favor of state or national health insurance. Whatever objections may be brought against such a scheme, its advantages in tuberculosis are obvious and incontestable. Last year a bill was presented to the New Jersey legislature for the relief of tuberculous families, allowing each dependent adult \$5 a week and each child under 14 years of age \$3. This pension was not to be distributed through municipal poor and alms departments but by the state department of health. The bill was presented too late to be included in the appropriation bill, and will be redrafted and presented this year. Special legislation for relief covering tuberculosis alone is a logical procedure until a scheme for insurance against all disease hazards is adopted.

ECONOMIC IMPROVEMENT

Improved Housing.—It is because the problems of economic improvement are spectacular that the public has learned to attach much importance to them. The economic side appears more national in character and has a wider appeal than any other view. The housing situation is the same in most cities that have a tenement or slum population.

The poor and destitute always gravitate toward the cheap tenements. The cheap tenement is badly kept up, is persistently insanitary, and escapes the control of tenement house commissions and local boards of health by constant change of ownership. Dark, damp, ill ventilated rooms are tolerated because they are cheap, and the tenants, fearful of eviction, will not complain. Few boards of health have a staff sufficiently large to inspect continually the conditions in all the tenements within the municipal area. Such buildings may be sanitary one day and indescribably foul the next. The only logical method of control is to pick out the plague spots and center intensive sanitary work on them. A list of tenement houses of a suspicious nature is most useful for local boards of health to have on record. The tenement house commission of New Jersey has adopted a score card for tenement houses which shows at a glance the structural condition of any one tenement building. These score cards will be available to local boards of health and will be a valuable index of housing conditions in these tenements, pointing out the worst places for intensive health work.

It is clear, however, that these insanitary habits are not necessarily confined to the poor and destitute, for tuberculosis is found in all stations of life. As Ritter says, "We may improve the most insanitary house or room, and make it habitable for either sick or well; but if we neglect to improve the occupant or occupants of the house, our efforts will be of no avail. Sanitation of the house must go hand in hand with personal and family hygiene."

Poverty is not the cause of tuberculosis; more truly poverty may be called the result of tuberculosis, for the disease by its long drawn out clinical history and the resultant physical incapacity is but a graduation from poverty to distress and family destitution.

The greater number of tuberculosis victims end their sufferings amid conditions of want and family neglect. The sick person has outstayed his welcome, his relatives are all working and will not have him, and the meager dole of municipal or voluntary organizations makes him

a human wreck most frequently beyond hope of salvage.

"The improvement in housing, the abolition of old tenement buildings, and the erection of new, light, sunny and well ventilated dwellings have been urged as the panacea that will exorcise the tuberculosis demon. This would be a worthy proposition if a similar change could be assured in the people thus translated from a bad to a good environment."

Ritter¹ supplies his own answer:

Now if such a supposed or active tuberculous individual were suddenly placed in a most hygienic room with plenty of sunlight and fresh air, a complete change of his environment, how long would these improved conditions prevail? . . . Would the occupant improve in his new surroundings or would the room rapidly retrograde? In all probability in a very short time we would find this sanitary, hygienic surrounding and well aired room in a most insanitary condition.

Industrial Hygiene.—For the control of tuberculosis, many fads have held sway. The effect of dusty trades on the prevalence of the disease has perhaps been unduly emphasized. Giving all due credence to the harmful effect of foreign matter on lung tissues, there is insufficient evidence to show that mechanical injury to the lungs is the frequent precursor of infection. As Bonney² remarks:

There are many other pursuits exhibiting a frightful mortality rate from tuberculosis in which inhalation of dust from any source cannot be regarded as a definite etiologic factor. . . . It is quite as reasonable to attribute the development of consumption to the effect of the ten or fourteen hours spent in the home as to the eight or ten passed in the workshop.

There are, it is true, trades and occupations which predispose to tuberculosis. Vast strides have, however, been taken in late years to improve the conditions in factories by the state department of labor. The effect of dust and fumes has been reduced to a minimum by effective mechanical devices, and there are few factories at this time in which dust is allowed to exist so as to be a serious hazard to health. The workers themselves with the aid of their trade unions are demanding better working conditions in factories and workshops. There is, however, much room for improvement in the working conditions of labor which only boards of health can properly supply.

The sanitary survey shows the diseases of occupation, the hours of labor and the special employment of women as subjects that can best be cared for by a bureau of industrial hygiene. At least diagnostic clinics are advised where expert advice may be obtained free or for a small charge.

ASSOCIATED ACTIVITIES

The importance of associated activities is evidenced by the control of epidemics bringing about a lessened prevalence of diseases such as measles and whooping cough. Child hygiene activities are important in protecting the mother, whose weak condition after childbirth or disease may well predispose toward tuberculosis. Convalescent homes for the treatment of hospital patients to insure good recovery before they return to their homes will surely be an added link in the chain of protection. Mental hygiene, our newest

1. Ritter: Bull. Chicago Tuberculosis Institute, 1916.

2. Bonney, S. G.: Pulmonary Tuberculosis and Its Complications, Philadelphia, W. B. Saunders Co., 1910.

health activity, will function to reduce the subnormal conditions harmful and prejudicial to the health of the family.

CONCLUSION

Finally, let me paraphrase a well known health motto:

"Freedom from disease is purchasable: within certain limits a community may by its own endeavors control tuberculosis in its midst."

51 Cypress Street.

THE SELECTION OF OPERATION FOR EXOPHTHALMIC GOITER *

W. E. SISTRUNK, M.D.

ROCHESTER, MINN.

Surgery, at the present time, gives a higher percentage of cures than any other measure in the treatment of exophthalmic goiter. For a number of years the mortality following surgical procedures has gradually decreased, largely because much has been learned regarding the selection of the type of operation which is safest in any given case, and because the greater number of patients are operated on earlier in the course of the disease than formerly, and at a time when they are better surgical risks. It is possible to operate by present day methods in a large number of consecutive cases of exophthalmic goiter without a death. There are, however, a few patients who fail to respond to preoperative medical treatment and who must be subjected to operation at a relatively high risk, in order to offer a chance for cure. Refusal to operate in this group of cases naturally diminishes the death rate. On the other hand, poor judgment in selecting the type of operation which is best and safest in a given case, and in advising operation in certain cases that are nonsurgical at the time, increases the mortality.

If the disease is left to run a normal course, it progresses in several different ways. In a few instances the onset is sudden, with rapid development of symptoms, and the progress is so quick that the patient soon becomes a poor surgical risk. In the greater proportion of patients, however, the onset of the disease is so gradual that in its incipency it can scarcely be recognized save by one highly experienced in the diagnosis of hyperthyroidism. In such patients the symptoms gradually increase in number and severity, and an enlargement of the thyroid gland occurs. As a rule the disease reaches its height during the second six months of its course, and the patient passes through a period which usually is referred to as a crisis. During such periods all the symptoms become markedly exaggerated; the pulse rate is high, there is rapid emaciation and loss of weight, with extreme nervousness and mental irritability, and often vomiting and diarrhea; marked damage occurs to the vital organs, such as the heart, liver, and kidneys. Unless the disease proves fatal, the majority of patients improve greatly after a period of from one to several weeks, although as a rule they are never so well after having passed through a crisis as they were before. The amelioration of symptoms may persist for a period varying from a few months to several years, but in the majority of patients a second or even a third crisis eventually develops. With each crisis the damage to vital organs,

especially the heart, liver, and kidneys, increases, until the patient finally suffers more from the symptoms produced by these degenerative changes than from the disease itself. In a third, but small group of patients, the disease runs a chronic course from its onset without the development of acute crises.

Fortunately and unfortunately, patients improve when treated medically: fortunately, because patients unfit for surgical treatment may improve to such an extent that they become fairly good surgical risks; and unfortunately, because a knowledge of the fact that improvement occurs under medical treatment leads many practitioners to use only medical measures in the management of exophthalmic goiter, apparently without fully realizing the sad state to which a large percentage of the patients thus treated will be ultimately reduced. Many patients who have been treated medically for a long period apply for surgical aid and are found to have such marked degenerative changes in their vital organs that it is impossible for surgery to effect a cure. Operation usually stops the progress of the disease even in this stage, but the damage to the vital organs cannot be repaired; it would be quite as reasonable to expect to cure patients with well pronounced nervous lesions from tertiary syphilis by means of antisyphilitic treatment.

It is often a perplexing problem to decide just how toxic a given patient is and how much damage has been produced by the disease, and for these reasons it is difficult to decide what operative procedures the patient will safely endure. Although the mortality is largely affected by the decision, no absolute rules can be given as to the selection of the best type of operation; each case must be judged on its own merits. A condition which in one patient would justify the performance of a thyroidectomy, in another patient would be counterbalanced by some other factor that would make the operation dangerous. There seems to be no way of elucidating all the possible conditions that may arise, as these can be recognized only by observers who are highly experienced in dealing with exophthalmic goiter.

In operating in such cases at the Mayo Clinic, certain factors are taken into consideration in selecting the type of operation. The ideal surgical procedure in exophthalmic goiter is partial thyroidectomy as soon as the first symptoms of the disease appear and it can be definitely proved, by metabolic tests, that hyperthyroidism is present. At this stage of the disease, a primary thyroidectomy can usually be performed with a very low death rate, and many such patients are restored to normal health. The percentage of patients operated on during the early stage of the disease is steadily increasing, and an increase in the percentage of cures will result.

It cannot be denied that certain patients improve and apparently recover under medical treatment. However, in the beginning of the disease it is impossible to distinguish between the patients who may fall in this group and those who are destined to suffer severe damage as the disease progresses. Great responsibility is assumed, therefore, by advising medical treatment in early cases, in which thyroidectomy might prevent the severe conditions and in many instances the death of patients who would fail to improve under medical treatment.

The metabolic rate is a definite index to the degree of hyperthyroidism in a given patient at a given time. It is of very great value as a diagnostic aid in the early stages of exophthalmic goiter, when studied in con-

* From the Mayo Clinic.

junction with the symptoms and general appearance of the patient. As a rule, the clinical picture presented by the patient, the metabolic rate, and the pulse pressure run hand in hand, the symptoms increasing and decreasing as the metabolic rate varies. However, patients do not always present the same clinical picture while carrying similar metabolic rates; for instance, one patient with a rate of $+50$ per cent. may be in a crisis and extremely ill, while another with the same rate may show a very different clinical picture and be a fair surgical risk. Some persons seem to develop a certain tolerance to increased metabolism. We occasionally see a patient who, although carrying a safe metabolic rate, must be classified as a bad surgical risk. Later, the same patient, while carrying the same rate, may present a different clinical picture and stand the operation which previously was considered unsafe. In all instances in which a high metabolic rate is associated with symptoms indicative of a high-grade toxemia, such as nervousness, irritability, cardiac dilatation, high pulse rate, loss of weight and strength, nausea, vomiting and diarrhea, the condition must be looked on as serious and nonsurgical. The metabolic rate gives no indication of the amount of damage which may have been done previously; it can be used only partially as a means of deciding on the best type of operation to be performed. We make a careful selection of the type of operation for patients with a rate above $+40$ per cent., and we hesitate to perform a primary thyroidectomy in patients with metabolic rates 60 to 70 per cent. above normal. In the majority of such patients without marked cardiac damage, and who, except for this high rate, would seem good risks, we perform a preliminary ligation as a means of testing their ability to stand any operative procedure without the precipitation of an acute hyperthyroidism. If a mild reaction follows the ligation, a thyroidectomy is performed after seven or eight days; but if the reaction is severe, it is best to do a second ligation and to wait three or four months before performing a thyroidectomy.

Certain patients, after having had the disease for some months, present themselves for treatment because of increased symptoms. As a rule they have lost weight and probably are losing weight at the time. Such patients will usually be found to have high metabolic rates. If the loss of weight and general strength has been marked, and especially if the patients are highly nervous and irritable, we have found that a thyroidectomy is performed with considerable risk because in these cases a crisis may be precipitated by even a slight surgical procedure. In such instances we usually perform two superior polar ligations, under local anesthesia, at one operation or at intervals of seven or eight days, and wait for three or four months before performing a thyroidectomy.

Patients who consult us during acute crises are considered extremely dangerous surgical risks, and we prefer to treat them by means of rest, fluids and careful nursing until the crisis is passed and there is a gain in weight, with a corresponding subsidence of the pulse rate, the nervousness, and mental irritability. The metabolic rate usually drops considerably following a crisis; therefore, patients who have just passed such a period are not likely to be thrown into an acute hyperthyroidism by a thyroidectomy; but on account of the marked degenerative changes in their vital organs and the weak, degenerated heart muscles, the operation may prove a dangerous procedure. In such patients

we have usually found it safer to perform two superior polar ligations, under local anesthesia, seven or eight days apart, thus preparing the way for thyroidectomy several months later.

In a few patients who seem to be risks for any surgical procedure and who fail to respond to medical treatment sufficiently to warrant an operation, we occasionally are able to perform two ligations at intervals of from seven to eight days after having made one or two injections of quinin and urea hydrochlorid solution or of hot water, into the thyroid gland. Such injections seem to lessen the tendency to excessive reaction following ligation.

It will be noted that ligation is performed with two ideas in view: first, as a means of testing patients who seem fit surgical risks for thyroidectomy but concerning whom there is enough doubt to make ligation the safer procedure, and second, as a means of preparing patients for thyroidectomy.

Patients who are being tested and who stand a ligation well can, in the majority of instances, stand a thyroidectomy. The reaction following the ligation of one superior pole, performed under local anesthesia, is similar to, but much less marked, than that which occurs when a thyroidectomy, instead of a ligation, is done. This reaction consists of an increase in the pulse rate and temperature, vomiting, nervousness, and mental irritability; it usually begins within a few hours after the operation has been performed, gradually increases, and reaches its height within from thirty-six to forty-eight hours. In exceptional cases it may be so marked as to produce death from an acute hyperthyroidism in from one to four days following operation. As a rule, however, it begins to subside after from forty-eight to seventy-two hours and, in a few days, the patient is in a state similar to that present before the operation. In cases in which the reaction following such a ligation is marked we perform a second ligation, and later a thyroidectomy.

When ligation is done with an idea of preparing patients for thyroidectomy, the superior pole is ligated on each side, under local anesthesia, at intervals of seven or eight days, and the patient is allowed to wait for three or four months before a thyroidectomy is done. During this period there is usually a marked abatement of symptoms and an increase in weight averaging about 21 pounds for each patient, while the general improvement is such that a thyroidectomy may be done with comparative safety. As a matter of fact, in some of these cases the surgeon hesitates to recommend a thyroidectomy; but experience has shown that hyperthyroidism may recur in from one to five years unless a thyroidectomy is done.

The degree of improvement which follows thyroidectomy depends largely on the extent of damage to the vital organs at the time of operation and on the amount of thyroid tissue which is removed. If the damage to organs has been extensive, it is impossible to restore the patient to normal health; the operation usually stops the hyperthyroidism and great improvement follows, but the organs do not return to normal. In doing a thyroidectomy on a patient with exophthalmic goiter, we have found that in order to bring the metabolic rate to nearly normal it is necessary to remove all of one lobe, the isthmus, and the greater portion of the other lobe, leaving a piece of gland tissue probably not larger than one half or one third of a normal sized lobe. If not enough thyroid tissue is removed, and this may be proved by metabolic tests,

the patient may be benefited, but will continue to have symptoms of hyperthyroidism. In a few patients, the remaining portion of the thyroid gland hypertrophies and the symptoms recur. In either case, if the metabolic rate indicates a degree of hyperthyroidism which seems incompatible with good health, we reoperate and remove a portion of the thyroid tissue which was left at the first operation.

LETHAL DOSE OF ROENTGEN RAYS FOR CANCER CELLS *

FRANCIS CARTER WOOD, M.D.

AND

FREDERICK PRIME, M.D.

NEW YORK

Within the last few years, and especially since the introduction of the Coolidge tube, much has been accomplished in the establishment of suitable dosage for the therapy of superficial and benign skin lesions

The difficulty of accurately measuring the dosage of roentgen ray compelled the repetition in 1918 and 1919, of much of the previous work; but the ultimate figures are quite concordant with the preliminary ones, the slight differences being largely attributable to a more efficient transformer which was substituted for the one first used, and to the more accurate measurement by ionization methods of the roentgen-ray output.

In most of the investigations which have previously been made on tissues under these conditions, very soft rays were used, the penetration of which was limited, so that a large dose could not be given the deeper tissues without destruction of the skin, as was well shown by the experiments of Wedd and Russ.¹

Quite recently, Kimura² published an account of a number of radiation experiments, but in all his series he also used very soft unfiltered rays, with a spark gap of from 4 to 8 cm. Such soft roentgen rays have, as just stated, a practical therapeutic value only on superficial growths, the penetration being very slight; and the general tendency at present is to use highly filtered rays with a spark gap of from 8 to 9 inches,

Fig. 1.—Results of exposure of mouse sarcoma 180 in vitro to one-fourth dose of roentgen ray, 85 kilovolts strength, at 23 cm. distance, with 3 mm. aluminum filter.

Fig. 2.—Results of exposure of sarcoma 180 in vitro to roentgen ray, 85 kilovolts, 5 milliamperes strength, at 23 cm. distance, with 3 mm. aluminum filter.

with the roentgen ray. The lethal dose for cancer cells, however, has not, so far as we are aware, been accurately determined for filtered rays of short wave length such as are now used for deep therapy. The experiments described below were, therefore, undertaken in 1916, with tissue growing in culture as well as in the living animal.

There is a distinct advantage in the use of animal tumors, as they furnish an easily reproducible standard for biologic calibration of the output of any roentgen-ray machine and of the effects of filters, while human material is extremely variable in its resistance to the rays, ranging from the basal-cell epitheliomas, which often yield to a single erythema dose, to the chondrosarcomas and fibrosarcomas, which are much more resistant than healthy tissue and in many instances cannot be influenced by any quantity of roentgen ray which does not endanger the life of the patient.

representing a terminal voltage across the tube of from 80 to 90 kilovolts. When low voltage is used, the effective roentgen-ray output from a tungsten target tube is small, the K radiation appearing only when about 70,000 volts are applied to the tube terminals, while a much higher yield is apparent with from 80 to 95 kilovolts.

Since this work was completed, German journals have been received containing reviews of a monograph by Krönig and Friedrich,³ unfortunately at present available only in abstract, and also two papers by Seitz and Wintz.⁴ Both groups of investigators used ionization apparatus to measure the dosage of roentgen ray, and report that they have determined the carcinoma

and sarcoma "dose." These determinations were, it is stated, made on human carcinoma and sarcoma, and the dose was determined by Krönig and Friedrich as "the amount causing shrinkage of a carcinoma nodule." This is slightly less than a skin erythema dose, employ-

much as 20 per cent., with the same transformer and tube, owing to fluctuations in the commercial current supply and variations of an unknown sort in the transformer and its regulating connections. It was found necessary to install a storage battery to heat the tube filament, instead of the usual low voltage transformer, as fluctuation on the line caused the tube to give off very irregular quantities of roentgen ray as measured in the ionization chamber, even when the variations in the milliamperage through the tube were slight.⁵

Our intention was to establish on easily transplantable mouse tumors the lethal dose of roentgen rays of moderately short wave length produced from a tungsten tube at a voltage which gave an ample yield of energy including the K series of lines and the short wave length region above it, the softer components of the general radiation being removed by a filter of 3 mm. of aluminum. This is the filtration most generally used for deep therapy, although, since its employment was suggested by Elihu Thompson in 1896, no scientific determination has been published showing exactly the thickness most effective on cancer tissue. Our experiments show no practical difference due to length of exposure. If one-fourth the dose is given for four times as long, the lethal quantity is the same (Fig. 1).

The same tumors were used in these as in previous experiments undertaken in this laboratory with radium instead of roentgen ray,⁶ i. e., mouse sarcoma 180, Crocker series, and mouse carcinoma 11, Crocker series. In addition, mouse embryo kidney was used, this offering a normal tissue as a check on the biologic effects of the rays. Sarcoma 180 is a rapidly growing, large cell sarcoma with but little interstitial tissue. It almost never undergoes spontaneous recession. Carcinoma 11 is a breast carcinoma of a medullary type, occasionally receding.

Fig. 3.—Tissue culture, sarcoma 180, exposed to four erythema doses of roentgen ray.

ing as they did 1 mm. of copper as a filter. Seitz and Wintz, using 0.5 mm. of zinc as a filter, found that the "carcinoma dose" is about 20 per cent. more than this. Such quantities of roentgen ray are about those which have for many years been known to be capable of causing the temporary disappearance of metastatic skin nodules of carcinoma of the breast with fair frequency. They are far below the amount required to affect primary growths of the same type. The latter authors state also that tumors vary in their susceptibility, a fact long known to every roentgenologist. They give their "sarcoma dose" as from 60 to 70 per cent. of that for a skin erythema; but their experience is confined to a few cases, and a wider knowledge will probably bring a realization of the fact that many sarcomas resist enormous doses of roentgen ray.

While the accurate estimation of roentgen rays with pastils of barium platinocyanid is difficult, if not impossible, they were, nevertheless, employed to furnish a rough approximation of the erythema dose. Graduated exposures over small areas were then made on the skin of the back of several patients, and the erythema dose for this region was obtained. This gives a universal biologic calibration of the amount of roentgen ray produced. The scale readings of a very sensitive galvanometer connected with an ionization chamber were then determined, and all conditions of current, voltage, distance, etc., were accurately recorded. With each series of experiments the apparatus was adjusted so that the same galvanometer deflections were again obtained. This is the easiest, simplest, and only satisfactory way with which we are acquainted of measuring the roentgen-ray output from a tube; and even though the results are probably not absolutely accurate, they are close enough for clinical work. The usual factors recorded, such as milliamperes through the tube, and the spark gap, give rise to errors, often as

Fig. 4.—Tissue culture, mouse embryo kidney, exposed to three erythema doses of roentgen ray.

In order to avoid the errors due to random fluctuations which occur when too small a number of animals

5. We are indebted to Prof. William Duane of Harvard University for valuable advice in connection with the ionization apparatus, which is of his design (Duane, William: *J. Cancer Res.* 4:72 (Jan.) 1919).

6. Wood, F. C., and Prime, F.: *The Action of Radium on Transplanted Tumors of Animals*, *Ann. Surg.* 62:751, 1915.

is used, from fifty to seventy-five animals, and often more, were inoculated in each series of experiments.

The tumors and the kidney tissue were removed under rigid aseptic precautions and cut into small pieces, averaging about 0.001 gm. in weight. These were moistened with a drop of Ringer's solution and placed in hollow slides divided by a small ridge of paraffin, on one side of which was the tissue and on the other a drop of Ringer's solution to prevent any drying of the tissue while undergoing treatment. The slides, which had been ringed with petrolatum, were then sealed by a cover glass, from 0.15 to 0.18 mm. in thickness, and another paraffin ring.

At the end of each exposure, half of the tumor tissue was inoculated into mice, and from the remainder in vitro growths in plasma were made. Control tumor series were made at the same time from unrayed tissue, and these also were inoculated into mice and grown in vitro. For the in vitro cultures a mixture of mouse serum and chicken plasma was used. Blood was drawn with a syringe from the heart of a mouse,

measured at skin distance, or twenty at half the distance. That such pastil readings have no biologic value may be judged from the well known fact that the color produced varies with the wave length of the roentgen ray used. For example, when the ionization chamber is employed, the deflections with the tube running as above were 160 mm. without a filter, and 55 mm. with 3 mm. of aluminum. In other words, the energy as measured by the ionization was as 1 to 3. A skin erythema was produced in ninety seconds and in eleven minutes, respectively, or in a proportion of about 1 to 7, while the pastil at 21 cm. required six minutes to reach teinte B with unfiltered rays, and eleven minutes with the filtered, a proportion of less than 1 to 2. Hence, statements like the one made by Wetterer⁷ that carcinoma is injured by a dose of three Holzknacht units is not only vague in form, but untrue unless the very softest rays are employed.

The pastil readings were finally made on a Cox radiometer, the Hampson and Holzknacht apparatus being found less satisfactory for our purposes. This, therefore, was the quality and quantity of roentgen ray used in the exposures, the time alone being varied.

SARCOMA

When sarcoma tissue was inoculated into mice immediately after exposure, it was found that when roentgen ray had been given for five, eight and ten minutes (a dose insufficient to produce erythema on human skin), and for twelve, fifteen and eighteen minutes, there was no appreciable difference in the number of tumor takes in mice or in the rate of growth between the control and treated tissue. In tissue that had been exposed for twenty-five minutes or longer, a gradual change was noticed; there was a decrease in the number of tumor takes and also in the rate of growth, which was much retarded, until after sixty minutes of roentgen-ray treatment there were no takes except in one instance. In the series which had been exposed to the action of the roentgen rays for seventy minutes, one tumor, out of forty-four inoculations, appeared at the end of four weeks. Similar "escapes" were noted in the studies on the radium lethal dose, published in 1917.⁸ There were no growths, however, among the grafts which had been treated for sixty-five minutes, nor among those treated for eighty minutes. It would seem, therefore, that in the majority of cases an exposure of between fifty-five and sixty minutes, or five or six so-called erythema doses, is usually sufficient to destroy the proliferative power of the cells of sarcoma 180, but not always, as is shown by the one growth appearing after four weeks, though the exposure in this case was from ten to fifteen minutes longer than was ordinarily required to kill all the cells. The percentage of grafts which grew after exposure to roentgen ray is graphically shown in Figure 2. As half the tumor particles did not grow after forty-five minutes, the broad assumption is permissible also that half the cells in the tumor would be killed by such exposure; it is, however, impossible to prove this.

SARCOMA TISSUE CULTURES

The tissues which were grown in plasma showed most interesting pictures. At the end of twenty-four hours there was a profuse growth in both the treated and the control tissue, which reached its maximum in

Fig. 5.—Tissue culture, mouse carcinoma 11, exposed to four erythema doses of roentgen ray.

without killing the animal, and the serum, after being allowed to separate, was diluted with Ringer's solution in the proportion of one part of serum to two parts of Ringer's solution, and to this mixture was added chicken plasma, one part to seven of the serum solution. The piece of tissue to be grown, either control or radiated, was placed in the center of a cover glass, and a drop of the serum-plasma mixture was added and spread out evenly with a needle; the cover glass was then inverted over a hollow slide which had previously been ringed with petrolatum, and in the bottom of which there was a drop of Ringer's solution, and the slide was finally ringed with paraffin. The series was incubated at 37 C., and observations were made at the end of twenty-four hours.

With the type of rectifying transformer employed, eleven minutes were required to produce an erythema reaction on the skin of the back of a human being at a distance of 23 cm. from the anticathode of a Coolidge tube, with 3 mm. of aluminum as a filter, while 5 milliamperes of current were used with a 21 cm. spark gap, an amount equivalent to five Holzknacht units mea-

7. Wetterer, Josef: *Handbuch der Röntgentherapie, nebst Anhang*, Ed. 2, Leipzig, O. Nemmich, 1913, p. 177.

8. Prime, Frederick: *Observations on the Effects of Radium on Tissue Growth in Vitro*, J. Cancer Res. 2: 107 (April) 1917.

about forty-eight hours. There was but little difference in the extent or character of the growth, whether irradiated or not, and even in the tissue which had been treated with roentgen ray for forty-five minutes there was always a profuse outgrowth of cells (Fig. 3). These outgrowths were carefully removed, and some were fixed in Zenker's fluid and stained with Delafield's hematoxylin, while the rest were inoculated into a series of mice. Tissue treated up to twenty-five minutes grew as did the controls; whereas after twenty-five minutes of irradiation the number of takes and the rate of growth diminished, until after forty-five minutes' exposure no growth occurred. Of the sections which were stained, some were studied just as they were fixed, and others were cut in serial sections. Mitotic figures in the nuclei were found to be very scarce, though some of the treated tissue in which no mitoses were found grew well. The finding of mitotic figures was not, therefore, always an indication of the power of the tissue to grow when inoculated into mice. The probability is that as cells are much more sensitive in the mitotic phase, only those in the resting stage survived and were able to grow.

Fig. 6.—Results of exposure of carcinoma 11 in vitro to roentgen ray, 85 kilovolts, 5 milliamperes strength, at 23 cm. distance, with 3 mm. aluminum filter.

Fig. 7.—Results of exposure of sarcoma 180 in vivo to roentgen ray, 85 kilovolts, 5 milliamperes strength, at 23 cm. distance, with 3 mm. aluminum filter.

Fig. 8.—Results of exposure of carcinoma 11 in vivo to roentgen ray, 85 kilovolts, 5 milliamperes strength, at 23 cm. distance, with 3 mm. aluminum filter.

NORMAL CELL CONTROLS

When mouse embryo kidney was used, the embryos were removed by operation as near term as possible. The kidneys were excised from the embryos and then treated in the same way as was the tumor tissue, except that no animal inoculations could be made. With this tissue there was a profuse growth, chiefly of connective tissue, in all the in vitro cultures which had been exposed to roentgen ray even up to forty-five minutes; beyond this, however, no growth took place (Fig. 4). No noteworthy difference could be observed between the treated tissue and the controls, except that after an exposure of twenty minutes to roentgen ray the growth was not quite so profuse as in the controls. There is, therefore, but little difference in the roentgen-ray sensibility of rapidly growing normal connective tissue cells and that of sarcoma cells. Clinically, fibrosarcoma is much more resistant than granulation tissue, while lymphosarcoma is more sensitive; hence, in estimating the radiosensitivity of human tumors the histologic type should always be known.

CARCINOMA

When mouse carcinoma tissue was exposed to roentgen ray in the same fashion, the results were slightly different. The tissue planted in vitro never gave rise to such profuse growths as arose from the sarcoma and kidney tissues (Fig. 5). The tissue was perhaps slightly more susceptible to the influence of roentgen ray than was sarcoma, and after an exposure of twenty minutes showed a diminution in its growth rate and in the number of takes when transplanted into other animals. An exposure of fifty minutes was required, however, before most of the tissue was killed, and even then there were two belated growths which appeared after the third week, showing that it is impossible, even when small pieces of tissue are treated, always to be sure of killing every cell, even though five erythema doses are given (Fig. 6). It should be remembered that neither roentgen ray nor radium kills the cells subject to its influence in a rapid manner. No doubt many of the cells exposed functionate for a few days, and spread out in culture in ameboid movements even when a dose which will ultimately be lethal has been administered.⁹

TUMORS EXPOSED IN THE ANIMAL

In order to determine whether the effect of roentgen ray on these tissues was influenced by the removal of ionization products and by a constant supply of fresh food to the cells, such as occurs when the tumor remains in the host, a number of mice bearing well developed tumors of sarcoma and carcinoma were enclosed separately in a small box and exposed to similar doses of filtered roentgen ray over periods varying from ten to ninety minutes. At the end of the treatment, the animals were killed, the tumors were removed under the usual aseptic precautions, and fragments from the portion of the tumor nearest the tube were inoculated through a hollow needle into a series of mice. The only difference in filtration was, therefore, the use of a millimeter or so of skin, instead of the thin cover glass used in the in vitro tests. It was found that fragments of sarcoma 180 which had been thus exposed for ten or fifteen minutes showed good

9. Prime, Frederick: Action of Radium on Embryo Heart Muscle. *Proc. New York Path. Soc.* 16: 56, 1916.

growth when transplanted into other mice; but after the animal bearing the tumor had been irradiated for twenty minutes there was noticed a slowing in the growth rate of the tumor after inoculation, which gradually increased until after sixty minutes there was no growth at all (Fig. 7).

When carcinoma 11 was exposed *in vivo* and then transplanted into other mice, it was found that slightly longer exposures to roentgen ray than in the case of sarcoma were required before any effect was shown on the growth of the tumors after inoculation. After sixty-five minutes' exposure the appearance of the tumor was delayed, but showed fair growth; and it was not until after an exposure of seventy minutes that no growth resulted (Fig. 8).

CONCLUSIONS

1. Approximately four erythema doses of roentgen ray, given continuously and filtered through 3 mm. of aluminum, are required to kill mouse carcinoma, and five to kill mouse sarcoma exposed *in vitro*; but occasionally some cells may escape the effects of even six doses.

2. Approximately six erythema doses of roentgen ray are required to kill sarcoma cells *in vivo*, as compared to five required to kill the same cells *in vitro*; and approximately six erythema doses are required to kill carcinoma cells *in vivo*, as compared to four required to kill the same cells *in vitro*.

3. The *in vitro* outgrowth from sarcoma tissue after four erythema doses of roentgen ray produced tumors when inoculated into mice.

4. At least five erythema doses of roentgen ray are required to kill carcinoma and sarcoma cells in tissue cultures, and at least four to kill embryonic connective tissue cells in cultures.

5. The amount of *in vitro* growth is no indication whether the tumor cell is or is not capable of proliferating in the animal body. The growth observed after lethal doses is evidently due to the slow action of the rays, which permits cells potentially dead to wander out into the medium and to complete a division process before their growth momentum is finally checked.

6. Absence of mitotic figures after roentgen ray treatment is not an indication of lack of ability of the cells to grow in the animal body.

7. The practical conclusion which may be drawn from these observations is that the amount of roentgen ray necessary to kill all the cells of a rapidly growing, very cellular, and highly malignant sarcoma or carcinoma in man is between five and seven erythema doses of filtered roentgen ray when the tumor is on the surface of the body. Every centimeter of tissue that covers the tumor makes an additional amount of roentgen ray necessary. For example, when slices of fibroid uterus are used as absorptive material, the galvanometer deflections show that at a depth of 2 cm. 19 per cent. more roentgen ray is required; at 5 cm. depth, 47 per cent. more, and at 10 cm. depth, 65 per cent. more. While many tumor cells may possibly be slowed in their progress and mitotic forms killed at such depths, it is doubtful whether all can be destroyed. The basal-cell tumors and the lymphosarcomas are, as is well known, much more susceptible to radiation. Small, superficial, metastatic carcinomas are also, in some instances, more susceptible than is the primary tumor.

DISLOCATION OF THE CARPAL SCAPHOID AND SEMILUNAR BONES

SAMUEL KLEINBERG, M.D.

NEW YORK

Dislocation of the carpal bones is a rare occurrence. A review of the literature shows that only very few cases of dislocation of the carpal bones have been reported. Inquiry among my orthopedic colleagues revealed that many of them had not seen a single case, while others had seen one or at most two cases during their entire experience. Fracture of the scaphoid, however, has been seen frequently, and there are a fairly large number of cases reported.

The two cases described below are reported, first, because of the rarity of the condition, and secondly, because a good functional result was obtained in the one case by operative removal of the dislocated bones, and in the other case by conservative treatment alone.

REPORT OF CASES

CASE 1.—History.—

H. B., a laborer, aged 21, fell from a fifth story window and injured his left wrist. It was impossible to obtain a history of the position of the hand at the time of injury. I first saw the patient about seven weeks after the injury. At that time, he complained of pain, swelling and disability of the left wrist, hand and fingers. The left hand and wrist were moderately swollen, the swelling being especially marked over the front of the wrist, where a mass of bone was easily palpable. This mass was directly under the skin, and was

Fig. 1 (Case 1).—Dislocation of scaphoid and semilunar of left wrist, lateral view.

freely movable in the lateral but not in the vertical direction. The styloid processes of the ulna and radius were in proper relationship. There was no tenderness or discoloration of any part of the wrist. The back of the wrist was moderately swollen, and palpation did not reveal any hollow. There was no voluntary motion in the wrist, but there was a passive flexion of about 20 degrees, and a few degrees of abduction and adduction. The fingers were not swollen but were in a flexed position, and their motion was much restricted. Forced extension of the fingers was painful. The grip was so weak that the patient could not hold even a light object. There were no sensory disturbances in the hand or wrist. The color of the hand and fingers was normal. The radial and ulnar pulses were present, and were easily palpable.

Examination.—A lateral roentgenogram of the wrist showed a dislocation of the scaphoid and semilunar bones upward and forward to a position anterior to the ulna and radius, as shown in Figure 1. The scaphoid was entirely above the radiocarpal joint line, while at least two thirds of the extent of the semilunar was above this line. The lower pole of the semilunar was also fractured. It is interesting to note

that these bones were entirely separated from the radius and other carpal bones: they had evidently torn through the ligamentous and muscular tissue in front of the wrist joint, and had become entirely subcutaneous.

Treatment and Results.—On account of the very marked displacement of these dislocated bones from the wrist joint, we considered that reduction by manipulation would be impossible, and that the best treatment would be the operative removal of them. Accordingly an anterior vertical incision was made over the wrist joint and the lower part of the forearm. The bones were found embedded in the subcutaneous tissue, and were surrounded by what appeared to be a fibrous capsule which had evidently been formed about them since their dislocation. None of the flexor tendons or the nerves on the front of the wrist joint were exposed.

Figures 2 and 3 are roentgenograms taken after the operation and show the appearance of the wrist minus the scaphoid and semilunar bones. This patient has been receiving baking, massage, manipulation of the wrist and exercises, and the function of the wrist and hand is rapidly improving. The mobility of the fingers has gradually increased, and he is now able to grasp and hold a 5-pound dumb-bell. The progress in the improvement since the operation has been continuous, and encourages us in the belief that the function may ultimately be normal. This is especially interesting in view of the serious disturbance of the wrist joint by removal of two of its component bones.

CASE 2.—History.—M. O., man, aged 35, was thrown from an automobile, injuring his right wrist. Immediately following the injury the wrist became moderately swollen, painful and

accident, when the persistent swelling, tenderness, pain and disability led to the taking of a series of roentgenograms. It is interesting to note that a roentgenogram of the wrist was taken a few days after the injury, a diagnosis of Colles' fracture was made, and reduction was attempted.

Fig. 3 (Case 1).—Lateral view of left wrist after removal of dislocated scaphoid and semilunar.

Fig. 4 (Case 2).—Dislocation of semilunar of right wrist.

Fig. 2 (Case 1).—Anteroposterior view of left wrist after removal of dislocated scaphoid and semilunar.

tender. The fingers were held flexed and were greatly restricted in their mobility. This man had suffered so many other and more serious injuries at the time that very little attention was paid to the wrist until several weeks after the

Examination.—Our roentgenograms show very definitely, as is seen in Figure 4, that the semilunar bone had been dislocated forward. The bone appears as a three-quarter moon, distinctly separated from and in front of the os magnum. It is rotated so that its inferior surface points downward and forward, and the superior surface points backward and upward instead of directly upward. The posterior border of the semilunar points downward, and the posterior half of the bone is in front of the os magnum. The upper articular surface of the os magnum almost touches the radius. The dislocation is not so complete as in the preceding case. In fact, it is only a partial dislocation or subluxation.

Originally the wrist was very much swollen and tender, and examination was not satisfactory. Several weeks after the injury when the swelling had subsided, palpation revealed a mass on the front of the wrist, and what was more interesting, a hollow in the middle of the back of the wrist. These findings are pathognomonic of dislocation of the carpal semilunar. There was a great deal of stiffness and pain in the wrist and fingers, and also numbness in the latter. Manipulation of the fingers was very painful. There was some voluntary motion in the wrist and fingers, which increased as the swelling subsided.

Treatment and Results.—Manipulative reduction under an anesthetic was refused. In fact, as the motion was increasing, and the disability became less pronounced, it was felt that conservative treatment would yield a good result. The treatment consisted in baking, massage, gentle manipulation and graduated exercises. The improvement has been slow but continuous, until at the time of this report the patient has almost perfect use of the hand and fingers.

The patient lacks as yet the normal strength of the wrist and hand, but he can write and perform all the finer motions of the fingers. There is at present no disturbance of sensation. There is no pain in the hand, except occasionally, and then it is not severe. However, it is important to remark that the pain did last for many months, and very much longer than in the first case in which the dislocated bones were removed.

1 West Eighty-Fifth Street.

THE TOURNIQUET

A MODIFICATION OF AN INSTRUMENT EMPLOYED
BY THE GERMANS IN THE LATE WAR

P. E. TRUESDALE, M.D.

FALL RIVER, MASS.

After the Germans had evacuated the Saint Mihiel salient, a metal tourniquet of unusual design was found in one of their advanced post surgical hospitals by Lieut.-Col. J. M. Flint and Lieut. A. Dayton.

The instrument was made on the principle of the clamp: both arms were of rounded steel and covered with rubber tubing. It was given to me for trial in Mobile Hospital No. 39, and I had the opportunity to use it many times. At first the tourniquet was found to be unsatisfactory because the construction of the handles was clumsy, and the blades separated widely when tightened over the limb, thus failing to control bleeding. In order to obviate this, it was necessary only to cross the arms of the instrument during compression.

There were two sizes, one for the arm and one for the thigh. When properly applied I found this tourniquet simple to adjust, safe in its effect on the tissues, definite in its control of bleeding, and very adaptable for the purpose in operations on the upper and lower extremities.

AUTHOR'S MODIFICATION OF
GERMAN TOURNIQUET

The instrument was sent to the office of the chief surgeon, and I did not see it again. However, the principle of the design was readily recalled, and I had one made by Codman and Shurtleff of Boston, as shown in Figure 1. It is the German instrument modified in several details that I found unsatisfactory. The arms of the new instrument are heavier and so shaped as to pass over the thigh more readily and to cross in closing about the limb (Fig. 2). The joint is strongly made, and the handles are given a direction which brings them nearly parallel when the tourniquet is applied. An oblong slot is made in the center of one handle, through which passes the adjustment screw. This part of the instrument is slightly curved so that when the thumb nut is firmly adjusted with the tourniquet in position, the adjustment screw may be shifted forward releasing compression, and back again for renewed control of hemorrhage, should that be necessary (Fig. 3). The fact that this release of compression can be made without releasing the thumb nut gives one an opportunity in a simple manner to examine the stump quickly for vessels that have not been ligated, or momentarily to allow blood to enter the limb during other operations that are more prolonged.

NECESSITY OF CONTROLLING HEMORRHAGE

Surgeons in all periods of history have sought the most efficient means of restraining hemorrhage. From the exigencies of war have come the multiplicity of

measures and apparatus of which we have knowledge. When one realizes that three fourths of those who die on the battle field perish from hemorrhage directly, or from shock as a result of excessive loss of blood, it is evident why the problem has demanded the utmost thought and consideration in all ages.

Tourniquets employed in civil practice are almost without exception the products of war, or ideas which have arisen from the study of military surgery; and now that the greatest war of all times is passing into history, it is logical that surgical thought should become more accurately focused on the causes of surgical failures in the field and on a study of the principles thus learned so far as they apply to surgery in civil life.

It is common knowledge that nature stops hemorrhage from small vessels and not infrequently from arteries of large caliber. This is brought about by the natural process of retraction of the severed ends into the surrounding cellular tissue, and by contraction of the circular fibers so as to diminish the caliber of the vessel. In bleeding from vessels of large size, this process is not sufficient. The blood then becomes coagulated in the cellular sheath. By diminishing the area of the sheath and producing increasing pressure on the open artery, the flow of blood is retarded, allowing coagulation to continue both within and without the artery, thus closing the end of the vessel.

It is well to remember that air favors coagulability of the blood and contraction of the vessels. Thus, internal hemorrhage from vessels of moderate size is more often fatal than bleeding from vessels of the same size which are near the surface of the body. Syncope delays hemorrhage from superficial vessels, but it may recur on the return of normal blood pressure, so that such liability should not be overlooked.

It is generally known that in full flight a bullet may divide an artery like a knife, and fatal hemorrhage may ensue, and that when a large vessel is divided by a sharp instrument the loss of blood is massive,

continuous and usually fatal unless the bleeding from the artery is promptly blocked by clotting of the blood between the vessel and the skin. Then pressure causes cessation of hemorrhage as just described. On the other hand, the immediate loss of blood may be only slight when complete division of the vessel is produced by a projectile, or by a spent ball tearing its way through the vessel walls. When an artery thus divided contracts, its torn intima is brought together at several points, thus aiding the formation of a blood clot. MacLeod¹ remarks:

A considerable artery may be fairly cut across and give no further trouble beyond the first gush of blood which takes place at the moment of injury. In such cases the vessel contracts and closes itself. If only half divided, as it is apt to be by a shell or the quick passage of a ball, then the hemorrhage will be in all probability fatal.

Fig. 1. Modified tourniquet.

DEVELOPMENT OF THE TOURNIQUET

Among the artificial methods of arresting hemorrhage, the tourniquet has been employed almost universally since the French surgeon, Morel, first applied his own invention of it at the siege of Besançon. It consisted of three parts: (1) a yard and a half of strong worsted, an inch broad; (2) a pad of leather, tightly stuffed with horsehair having a loop on one side of the band to slide through, and (3) a piece of strong leather having two apertures an inch apart through which the band or ligature is passed. This tourniquet was made on the principle of creating the maximum pressure over the vessel by the use of a pad, instead of a strong general pressure around the limb as produced by a rubber bandage or elastic ligature. The latter was the method commonly used by the American forces in the recent war. All other tourniquets in use are simply modifications of the original instrument of Morel. Petit's tourniquet was the Morel appliance with a screw adjustment, a strap, a buckle and a compress. In addition there was a clamp, or horseshoe tourniquet, Dupuytren's compressor, Charriere's tourniquet, Skey's, Moore's, Tyrell's, Lambert's, and the like.

The field tourniquet employed in the Civil War was a sort of "garrot" or "Spanish windlass" and did not differ materially from that used in former wars. S. D. Gross² thus wrote on this topic:

It is not necessary that the common soldier carry a Petit's tourniquet, but every one may put into his pocket a stick of wood 6 inches long and a handkerchief or a piece of thick compress and be advised how, when and where they are to be used. By casting the handkerchief around the limb and placing the compress over the main artery he can by means of the stick produce such an amount of compression as to put at once an effectual stop to the hemorrhage. This simple contrivance, which has been instrumental in saving the lives of thousands, constitutes what is called the "field tourniquet." A pipe, knife or ramrod may be used if no special piece of wood is at hand.

The tourniquet of Petit was widely employed in civil practice, and is still used today in many French hospitals.

DISADVANTAGES OF MOST TOURNIQUETS

Whenever a wounded soldier was brought to our operating room in France with a tourniquet firmly applied, I was apprehensive always about the vitality of the limb and its capacity to resist infection. I believe that this feeling was shared by most surgeons who were operating in the advanced zone of the army. This attitude prevailed among surgeons of the Civil War, for Prof. Charles A. Lee³ stated that a brigade surgeon who was at the Battle of Bull Run, where more than 2,000 were wounded, informed him that the use of the field tourniquet was so frequently followed by mortification and loss of the limb that he had come to the conclusion that it was far safer to leave the wounded to nature with no attempts to arrest the flow of blood, than to depend on the common army tourniquet.

The firm application of a tourniquet for more than an hour usually meant trouble of some sort, either an intolerable degree of pain, imperfect retraction of the muscles after amputation, phlebitis, infection or gangrene, so that in some areas on the western front anything more than the temporary use of the tourniquet to control profuse bleeding was prohibited. Many of the tourniquets which I had occasion to observe on wounded soldiers were too tight or too loose or very difficult to release without removing the appliance entirely.

ADVANTAGES OF THE METAL TOURNIQUET

The metal tourniquet obviates the dangers incurred by the use of the elastic band, the elastic ligature or the various forms of a windlass control. Simply by shifting forward the adjustment screw, releasing the compression and allowing blood to enter the limb for a few seconds, at short intervals, this tourniquet may be carried effectively and without danger for many hours.

It is obvious that the ordinary soldier could not be burdened with this instrument, but it could go with the stretcher bearers and be provided in every advanced dressing station.

The same principles govern the use of compression for restraining hemorrhage in war as in civil surgery where some form of the elastic ligature is the appliance now most popular in use. When applied, such a tourniquet is generally too tight or too loose, the degree of compression depending on the strength and will of the individual adjusting it. Its application should be the last thing done before the incision is made, and it should be released as soon as the main vessels are taken up by hemostats. But the tourniquet is frequently put on before the surgeon is ready to operate, and once applied it is easily forgotten during the exigencies of an operation. A nurse can be instructed readily in the management of the metal tourniquet, and in operations other than quick amputations she will release the compression for ten seconds every ten minutes by shifting the adjustment screw forward, and the operation may proceed for from one to two hours with only slight inconvenience to the operator and complete

safety to the vitality of the limb. The duties of the nurse in the management of the tourniquet are definite, and the same degree of reliance can be placed on her intelligence for this purpose as we have learned to accord her in the administration of anesthesia.

The metal tourniquet should be sterilized with the other instruments. With the prepared area extended to Poupart's ligament and the gluteal fold, the instrument is placed in position within the sterile field and over a folded towel which encircles the thigh. Immediately before the operation is begun, the leg is elevated and firm compression made by adjusting the thumb nut. Further management of the clamp has been referred to above. Rubber tubing may be used on the arms of the instrument, if desired.

Secondary hemorrhage, the bane of the surgeon in operations involving infection of the tissues contiguous to the larger vessels of the extremities, is not altogether a historic vision. It is relatively uncommon, but none

3. Lee, C. A.: *A Description of the Elastic Tourniquet*, New York, George F. Nesbitt & Co., 1862.

the less dreaded by surgeons of today, as it was by those of former times. Arterial ulcerations still occur as a result of erosion from mechanical irritation, compression for sequestrums in fractures, osteomyelitic foci, and prolonged contact with rigid draining tubes. Hemorrhage from these causes has no tendency to be arrested spontaneously.⁴ When secondary hemorrhage occurs from a large vessel, little can be done in time to save life unless a surgeon is near by. Under such circumstances the average nurse can accomplish little with

Fig. 3.—Handles of tourniquet: A, slot through which adjustment screw B passes; heavy lines represent adjustment screw holding clamp in position of compression with thumb nut C set; broken lines represent adjustment screw shifted and compression released.

the elastic tourniquet. Before the patient is exsanguinated, the nurse must act swiftly with a simple and trusty instrument of compression. On such occasions the speed with which adequate compression can be applied decides the issue between life and death.

"Simplicity, not complicity, of surgical instruments on service," though not a modern expression, is as truly the object to be aimed at today as it was many years ago when urged by Sir John Hall, inspector general of hospitals in the British army.

dilute solutions. Practically, this is found to hold good, as a one-third molecular solution of iodoform in ether casts a shadow of the same density as a molecular solution of either potassium or sodium iodid. Owing to the fact, however, that it is insoluble in water and only sparingly soluble in fixed oils, it cannot be used to advantage. Iodoform emulsions can be prepared, but do not prove satisfactory.

Thymol iodid (aristol) was also found to be inadaptable on account of its insolubility and low iodine content (46.1 per cent.).

Water soluble salts of erythrosin (tetra-iodo fluorescein), even though each molecule contains four atoms of iodine, are unsuitable for use on account of their relatively low percentage of iodine and because of their high cost. This also serves to show that complex organic compounds of high molecular weight contain a lesser percentage of iodine or bromine than simple inorganic salts, in spite of the fact that the former contain more halogen atoms per molecule.

Eosin is too low in bromine and too expensive to be used in stronger solutions.

The inorganic salts of bromine and iodine are superior to their organic compounds in every way. From the standpoint of opacity, the iodides are better than the bromides because iodine has an absorption value considerably higher than that of bromine. It follows that the iodides can be used in weaker solutions and consequently cause no more irritation than the stronger bromide solutions.

At present the bromides cost considerably less (68 cents a pound) than the iodides (\$4.05 a pound).

STRENGTH OF PASTES USED

When comparing various substances as to their absorption values, molecular solutions are used. For routine use, percentage solutions are preferable.

In the test tube, an alcoholic solution of iodine crystals, less than 5 per cent. in strength, does not cast a well defined shadow. For this reason a solution of an iodide should contain more than 5 per cent. of combined iodine to be sufficiently opaque. Thus, a 10 per cent. aqueous solution of sodium iodide contains 8.46 per cent. of combined iodine and casts a good shadow.

For the injection of chronic sinuses, etc., it is well to keep well above these limits. Iodide pastes can be made

TABLE 1.—PERCENTAGE OF IODINE OR BROMINE IN VARIOUS SUBSTANCES USED

Potassium iodide (KI).....	contains 76.4% iodine
Sodium iodide (NaI).....	contains 84.6% iodine
Iodoform (CHI ₃).....	contains 96.8% iodine
Dithymol-iodide (C ₂₀ H ₂₀ O ₂ I ₂).....	contains 46.1% iodine
Potassium bromide (KBr).....	contains 67.1% bromine
Sodium bromide (NaBr).....	contains 77.6% bromine
Eosin (C ₂₀ H ₁₆ O ₅ Br ₄ Na).....	contains 47.6% bromine

to vary from 15 to 30 per cent., and bromide pastes from 25 to 40 per cent. in strength. For routine use, a 15 per cent. iodide or a 25 per cent. bromide paste is sufficient.

PREPARATION OF PASTES

A serviceable paste should have these characteristics:

1. It should be nonirritating.
2. It must be thick enough at body temperature, to be retained when injected.
3. It must be free from small lumps as often it is desirable to pass it through a medium sized needle.
4. Its base should be water soluble so that it can be easily washed from an injected area.

IODIDE AND BROMIDE PASTES AS USED IN ROENTGENOGRAPHY

PRELIMINARY REPORT

ROBERT F. SCHANZ, M.D.

FORT WAYNE, IND.

Since Cameron¹ found that watery solutions of the iodides of sodium and potassium could be successfully used as opaque mediums in roentgenography, it has also been found at the Mayo Clinic that the bromides can be used to the same advantage. At present from 12 to 25 per cent. solutions of these salts are being used for cystograms and pyelograms. Similar solutions can also be used to great advantage for the injection of chronic tracts, sinuses, cavities and fistulas. A thin, watery solution, however, is difficult to retain long enough to obtain good roentgenograms.

With the idea of finding a suitable medium for injection purposes, I undertook a systematic study of various pastes for the incorporation of iodine and bromine containing substances. Organic compounds such as iodoform, eosin and erythrosin, which contain either iodine or bromine, are inferior to the simple inorganic salts.

IODINE OR BROMINE CONTENT OF VARIOUS COMPOUNDS

Table 1 expresses the percentages of iodine or bromine in the various substances used.

Theoretically, iodoform containing three atoms of iodine in each molecule should be opaque even in more

4. Keen, W. W.: *Surgery, Its Principles and Practice*, Philadelphia, W. B. Saunders Company 5: 86, 1909.

1. Cameron, D. F.: *Aqueous Solutions of Potassium and Sodium Iodides as Opaque Mediums in Roentgenography: Preliminary Report*, J. A. M. A. 70: 754 (March 16) 1918.

5. It should be easily prepared and preserved.

I prepared pastes of starch, dextrin, acacia, Irish moss and tragacanth. Of these, the following were found to be serviceable:

The corn starch is suspended in the water and is then placed on the water bath. It is stirred continuously until a thick paste forms. The glycerin is then mixed in thoroughly. Glycerin forms a glycerid of starch and also prevents the surface film from forming when the paste cools. Now 15 gm. of an iodid or 25 gm. of a bromid are added. These go into solution readily without the addition of more water.

TABLE 2.—STARCH PASTE

Corn starch	10 gm.
Glycerin	16 c.c.
Water	100 c.c.

To preserve the paste and to render it unfit for bacterial growth when harbored in a tract, 0.5 c.c. of pure phenol or 1 c.c. of a volatile oil, such as oil of thyme, is incorporated. To help the surgeon in following out the tract at the time of operation, the paste is colored a deep blue with a solution of methylene blue.

The moss is first well washed in cold water. It is then placed in a beaker, the water is added, and the whole is placed on the water bath for fifteen minutes. It must be stirred frequently. The resulting mucilage is strained

TABLE 3.—IRISH MOSS PASTE

Irish moss	3 gm.
Glycerin	6 c.c.
Water	100 c.c.

through muslin and the glycerin is added. This mixture is then heated on the water bath until a thick, jelly-like paste is formed. Then the iodids or bromids and the phenol are incorporated as in the starch paste. This paste seems difficult to color.

The water is added to the tragacanth, and the mixture is stirred thoroughly and allowed to stand for twenty-four hours. Then the glycerin is mixed in. It is heated on the

TABLE 4.—TRAGACANTH PASTE

Tragacanth (powdered No. 1)	5 gm.
Glycerin	8 c.c.
Water	100 c.c.

water bath for about thirty minutes. This is sufficient to make a thick jelly-like paste. Then one proceeds as in the other pastes.

SUMMARY

1. The simple inorganic salts of iodine and bromine are better and less expensive than the complex organic compounds.

2. The starch paste is the most economical, is quickly prepared, and is very serviceable. If carefully prepared, it is free from lumps.

3. The pastes made from tragacanth or Irish moss are more elegant but are more difficult to prepare. The air bubbles found in these are driven off by heat.

3. All of these pastes are nonirritating, are easily injected, and can be removed from the injected area at once by a stream of warm saline solution, if desirable. In the latter respect they possess a decided advantage over oily preparations.

4. They are retained long enough to permit good roentgenograms to be made. If the opening of a tract or sinus is plugged with cotton after the paste is injected, the latter can be retained until operation.

5. The pastes can be sterilized in the autoclave before the phenol is added and can then be put into collapsible tubes for future use.

THE TONSIL IN RELATION TO INFECTIOUS PROCESSES *

DAVID JOHN DAVIS, M.D.

CHICAGO

Some years ago when I became engaged in the study of focal infections, interest centered largely around joint and various rheumatic lesions, and the tonsil was receiving first consideration as the probable responsible focus and portal of entry. It early became clear that in order to justify many of the charges made against the tonsil, and to solve even some of the numerous problems arising in connection therewith, we were in great need of intensive studies on certain phases of the bacteriology and pathology of these organs. Even more, perhaps, than studies designed to relate infectious lesions in various localities to the tonsil as a focus, we needed fundamental studies on the bacteriology and pathology of these organs in normal persons. I wish here to present briefly certain studies along these lines.

DISTRIBUTION OF LYMPHOID TISSUE

An interesting point appears in connection with the distribution of lymphoid tissue in the throat and gastrointestinal canal in relation to the bacterial flora. It is well known that lymphatic nodes are so distributed as to protect the body against the absorption of dangerous matter from certain well-recognized sources. Indeed, lymphoid tissue occurs, generally speaking, only in those localities where such absorption is occurring. So we have the clusters of glands at the hilum of the lungs, in the mesentery, in the axillary and inguinal regions, etc.

In the alimentary tract from the lips to the rectum there are two localities where striking accumulations of lymphoid tissue appear, namely, in the region of the throat, and in the lower small intestine, especially about the ileocecal valve and appendix. The intervening localities, like the stomach, duodenum, etc., have lymphoid tissue, but it is irregularly distributed and far less in quantity. *A priori*, this would indicate excessive absorption of dangerous matter in the localities where lymphoid tissue is abundant, and as a matter of fact this appears to be true; for in the throat and in the region just above and below the ileocecal valve we find normally the greatest number and variety of bacteria. This can readily be shown by making smear and culture preparations at intervals along the alimentary canal. If one should represent the amount of lymphoid tissue along the canal by one curve, and the number of bacteria normally present by another, the two curves would in general parallel each other. Beginning at the mouth, the curves would rise rapidly, attaining a maximum in the pharynx; they would then descend in the region of the esophagus and stomach, only to rise again in the small intestine, gradually approaching another maximum about the ileocecal valve, and then descending somewhat toward the rectum, where many of the bacteria die.

PROTECTIVE MECHANISM OF LYMPHOID TISSUE

In the throat, the palatine tonsils represent the greatest single accumulation of lymphoid tissue, while in the intestine, the agminated follicles of Peyer and the appendix represent the same. The significance of these accumulations appears to be that of a protective mech-

* From the Department of Pathology and Bacteriology, University of Illinois College of Medicine.

anism against various products of absorption, bacterial and other.

In these two localities, not only is the normal bacterial flora more highly developed, but here occurs the greatest number of infections: in the throat streptococcus, pneumococcus, meningococcus, staphylococcus infections, the viruses of numerous exanthems and other diseases; in the lower intestine, typhoid, paratyphoid, dysenteries, tuberculosis, appendicitis, etc. In the intervening localities, relatively few infections occur. The pathogenic organisms attack primarily the lymphoid structures or, at any rate, the parts rich in lymphoid tissue. It would appear that in many instances these organisms become adapted to grow in lymphoid tissue—in other words, to attack the very mechanism which the body has apparently designed for protection against bacteria. Striking examples of this are the hemolytic streptococcus infections in the tonsil and typhoid infection of Peyer's patches. Lymphoid tissue thus may not be equally protective against all bacteria. In certain infections this mechanism breaks down entirely, and instead of being protective it furnishes a fertile soil for invasion. It is on account of the prevalence of certain infections in this tissue that it may be of advantage to remove this mechanism, or a part of it, as is done in tonsillectomy and in appendectomy.

SURFACE AREA OF THE TONSILS

Another point of importance in connection with tonsil infections is the surface area involved, since this is one factor in determining absorption of bacteria and their products. The epithelial surface of the tonsils is many times increased on account of the branching crypts penetrating deeply into the organ. We have attempted to measure the total surface, and find that roughly in an average tonsil of 2 by 1.8 by 1 cm., the entire epithelial surface would amount to about 25 sq. cm. This is only an approximation. Tonsils vary markedly in size, as also in the number and size of crypts; in hypertrophied tonsils, the surface would be far greater than this. Furthermore, the surface epithelium is loose and spongy, the round cells penetrating the layers even to the surface, giving rise to the well known epithelial structure of the crypts, interpreted and spoken of as a physiologic wound. While the extent and nature of the surface are important factors in any infectious process, it is not usual for all parts of the tonsils to be involved equally. When making smears and cultures from the individual crypts in a given tonsil, one is struck by the variation in the number and the kinds of bacteria from them. Some swabs may be sterile, others may contain many bacteria; in microscopic sections of diseased tonsils certain parts of the organ, or more often certain crypts, may show marked exudation and change, other parts or crypts revealing little or no significant alterations.

PLASMA CELLS

The distribution of plasma cells in the body is suggestive in connection with infections of lymphoid tissue. Generally speaking, these cells in the body are indicative of chronic inflammation or irritation, and most writers regard them as pathologic cells, at least when found in appreciable numbers. They accumulate in masses about centers of chronic inflammation, and in general are characteristic of granulation tissue. They appear in many low-grade inflammations of the skin and mucous membranes.

The tonsils and crypts become infected at birth or within a few hours thereafter. Even pathogenic organisms very early appear, *Streptococcus pyogenes* having been noted as early as ten hours after birth. The flora of the infant mouth is largely streptococcal.

Using the local accumulation of plasma cells as a possible criterion of the absorption of bacteria or their products, I studied the time of appearance and the distribution of plasma cells in tonsils. About 240 pairs were examined for these cells. As a routine, the methyl green-pyronin stain of Pappenheim was employed. One hundred and eighty pairs had been extirpated from children and adults, and about sixty pairs came from necropsies on subjects of various ages ranging from fetuses to the very aged; seventeen were from infants less than 3 months old.¹

The results briefly were as follows: These cells are not found in tonsils of the fetus or of the new-born. They make their appearance regularly about the second or third week, and are always found thereafter. In children several months old they are constantly found, usually in abundance. They are present throughout life and even to very old age (88 years) regardless of the anatomic condition of the tonsil. In pathologic tonsils, and especially in hypertrophy, they are very numerous. They occur under the epithelium of the crypts along the strands of connective tissue, and clustered about small blood vessels.

In view of the rôle that these cells play in general pathologic processes, and since they occur so regularly in tonsils a short time after the entrance of bacteria, one is led to suggest that their presence here indicates a chronic infection focus where absorption of irritating products is constantly occurring. Aschoff has noted the same facts in connection with the appendix. Along the entire gastro-intestinal canal, too, one observes large numbers of plasma cells under the mucosa and, especially in the region of lymphoid follicles. These facts are quite in harmony with the observations made by Adami and others on the more or less constant penetration of the mucosa by organisms and termed "subinfection." No doubt many bacteria are constantly passing through the alimentary wall into the lymphatics and blood stream, there to be disposed of in different ways. To these bacteria and their products after penetrating the epithelium, the plasma cells probably offer the first barrier or line of defense. In the sense, therefore, that the term subinfection has been used in connection with the condition of the so-called normal tonsil, or in the sense in which Aschoff uses the term "chronic inflammation in the appendix," we may regard all tonsils as chronically inflamed a short time after birth. One should, however, interpret rationally such findings in tonsils; and when the terms are used as above they should not necessarily convey the idea of a dangerous or serious pathologic state requiring surgical intervention. Nor should they be interpreted as a focus of infection in the sense in which that term is now commonly used.

BACTERIAL FLORA OF TONSILLAR CRYPTS

The statement is often made that the flora of the tonsils and the crypts is abundant and varied. This does not appear to be true. By no means will any or every germ that enters the tonsil live and develop there. Recently, in our laboratory, Miss Sexsmith tested the viability of a number of organisms in the crypts. After

1. Further details are given by the author in the *Journal of Infectious Diseases* 10:142, 1912.

careful cultures of a crypt for control purposes had been made, a few drops of a live bacterial suspension were injected into it by means of a curved blunt needle. Daily cultures then were taken of the crypt. *Bacillus prodigiosus* after injection gradually became less numerous, and at the end of the fourth day had completely died out. Injection of *B. pyocyaneus*, a pathogenic chromogen, caused a slight reaction in the throat lasting a day or two. The organisms gradually diminished in number, and by the fifth day had disappeared. *B. coli* will likewise disappear in the course of a few days. It is evident from these data that certain bacteria, even those well adapted to grow in certain parts of the body, will not flourish in the tonsillar crypts. In other words, it is not proper, as has been done, to look on the tonsil crypts as a cluster of culture tubes set in the upper part of the alimentary canal, growing numerous varieties of bacteria and discharging them into the lumen. As we shall see, the flora of the tonsils is a highly specialized one, restricted quite definitely to a few varieties.

From the anatomic structure of the tonsils, one might expect organisms requiring varying degrees of oxygen tension to thrive here. A few years ago I reported some work on the so-called actinomyces-like bodies often found in the crypts.² Since then, further work has confirmed the observations made at that time. These bodies are found in 30 per cent. or more of tonsils, and are composed of three kinds of organisms evidently growing together in symbiosis: fusiform bacilli, spirochetes and streptococci. The fusiform bacilli grow under anaerobic conditions, and in the crypts develop into a cluster of filaments, forming a central stalk about which the fusiform rods are arranged perpendicularly, closely resembling the structure of a test tube brush. Scattered throughout this growth are very large numbers of spirochetes, actively motile. The streptococcus forms in these masses have recently been studied in detail by Pilot and myself. There are hemolytic and nonhemolytic varieties. The hemolytic are aerobic and quite like the varieties that occur commonly in the throat. Many of the nonhemolytic streptococci from these granules are distinctly anaerobic when first cultivated. They exhibit a green halo on blood agar plates, and if the initial cultures are not made anaerobically they will not appear. After a few transplants under aerobic conditions, however, they will adapt themselves to grow equally well in the presence of oxygen. This anaerobic property of the green strains is very definite and is readily discernible in the first series of cultures. According to Holman's classification they belong to *Streptococcus mitis* and *Streptococcus salivarius* varieties. They are not highly virulent for rabbits, being comparable in this respect to the ordinary *Streptococcus viridans* of the buccal mucosa.

Fusiform bacilli.—*B. fusiformis* occurs in the crypts either in the granules as above described, singly or in small, loose, irregular clusters. In either form they are probably found in all tonsils at some time or other. They appear quite like the bacilli occurring about the teeth. I am inclined to the view that the crypts are the normal and usual habitat of these bacilli. From here they readily infect the mouth, especially the teeth, when these are not properly cleansed or are decayed or pyorrheic.

The possible relation of these bacilli to the infections included under the term Vincent's angina is interesting.

A preparation from a Vincent lesion is indistinguishable from one made from a tonsil granule. On the tonsil, Vincent's angina often begins about the mouth of the crypts, and may involve the sides. The question arises whether or not the fusiform bacilli of the tonsil crypts are a common source of the organisms in Vincent's angina, the crypts serving as the primary breeding grounds for them. These bacilli, together with streptococci, are a common cause of brain abscess resulting from bronchiectatic cavities in lungs, where these bacilli find favorable conditions for development. Presumably they pass down to the bronchi from the tonsils or teeth. Brain abscesses have followed tonsillectomy.

Streptococci.—Some years ago when studying the bacteriology of extirpated tonsils from certain cases of chronic infection, I noted a striking difference between the surface flora and the crypt flora of tonsils.³ On the surface the predominant organisms were of the *Streptococcus viridans* type, whereas the predominant organisms in the crypts of the same tonsil were as a rule hemolytic streptococci. The exceptions were few. The difference was so striking that at first I attributed great significance to this point, since the hemolytic varieties are so much more virulent as a rule than the green varieties. Later I found that most tonsils, regardless of the associated condition, contained a similar flora. Hypertrophied tonsils especially, but also others that show no noteworthy pathologic condition, reveal the same distribution of the varieties of streptococci on the surface and in the crypts. Pilot in our laboratory recently also examined 100 tonsils, extirpated chiefly for hypertrophy, though many were normal in size. Hemolytic streptococci were found on the surface in 61 per cent.; they comprised usually less than 10 per cent. of the total number of bacteria. In the same throats from which these tonsils were removed, cultures taken just before extirpation yielded 43 per cent. positives. Crypt cultures yielded 97 per cent. positives, and in almost all the hemolytic variety was greatly predominant. Furthermore, in another series of twenty-four normal persons, cultures from the throat and pharynx yielded hemolytic streptococci in 58 per cent.; in nineteen persons without tonsils, cultures similarly made gave positive results in 15 per cent., and in these persons were found either bad teeth or tonsil remnants.

It appears from these results that the crypts are an almost constant source of hemolytic streptococci, and this location may be considered in a way their normal habitat. We have not been able to find that any other part of the body so constantly harbors them. The throat, as we have known for a long time, is their chief source and habitat in the body, and it would now appear that the crypts of the tonsils usually supply the throat with these organisms. From the throat they may be distributed to various parts of the body by contact and otherwise. Or they may be transferred to other persons through the usual channels by which respiratory diseases are transmitted.

In the isolation of streptococci from crypts of tonsils, certain technical points should be kept in mind. In extirpated tonsils the organ should be cut lengthwise with a sterile, sharp knife; and then with a sterile forceps the crypts may be opened, more incisions being made if necessary, and cultures taken with a platinum

2. Davis, D. J.: J. Infect. Dis. 14: 144, 1914.

3. Davis, D. J.: The Pathology and Bacteriology of the Faucial Tonsils, etc., J. Infect. Dis. 10: 148, 1912.

loop from the depths of several crypts. It is necessary to do this for the reason that one crypt may be practically sterile and an adjacent one may contain many streptococci. This is not the rule, however; hemolytic streptococci when present at all are usually found in all or nearly all the crypts. Cultures of both tonsils should be made, since the organisms may be found on one side and not on the other. In tonsils from fresh postmortems the technic is essentially the same, and one finds the organisms commonly in such material.

In making cultures from tonsils *in situ*, certain difficulties are encountered. A small elongated loop of heavy wire should be inserted deep into several of the crypts, turned from side to side when in position, then carefully removed without touching other structures, and at once plated on blood agar. The green streptococcal colonies are usually present with the hemolyzers under these conditions, often in large numbers, since they are carried away on the wire from about the mouths of the crypts, where they are found abundantly. Excepting in acute infections of the tonsils, the cheesy or purulentlike material that exudes from the tonsillar crypts on pressure is no more, indeed is less, apt to contain hemolytic streptococci than the empty crypts. Much of the fluid material expressed from tonsils, enlarged or otherwise and commonly called pus, is not purulent when examined microscopically.

In conclusion, this point deserves emphasis: Nearly every one is harboring typical hemolytic streptococci in his tonsils which have not been differentiated from strains that cause serious infections, pneumonias, etc. Presumably such infections may or may not cause arthritis, iritis and other so-called focal infections; but finding them in the tonsil may mean nothing in relation to a possible systemic disease. Should one find abscesses or other definite pathologic lesions in the tonsils, a bacteriologic examination may be of value in determining the cause of an associated condition.

SUMMARY

In order to understand clearly the genesis of certain diseases, it is necessary to study intensively a suspected focus of infection, like the tonsil, in both normal and infected persons.

Lymphoid structures attain two maxima of distribution: one in the throat and another in the region of the ileocecal valve and appendix; these maxima correspond in general to the normal distribution of bacteria in the alimentary canal. At these points also the greatest number of pathogenic micro-organisms attack the body.

Plasma cells appear shortly after birth (therefore after infection) under the mucosa, and their presence probably indicates chronic absorption of infectious and other material.

Certain organisms injected into the crypts of the tonsils disappear in a few days. The flora normally found in the tonsils is a restricted one.

Actinomyces-like granules, composed of fusiform bacilli, streptococci and spirochetes growing together, appear as more or less normal inhabitants of the crypts. Here may be an important source of *B. fusiformis* in certain infections about the mouth caused by this organism.

In the tonsil crypts, *Streptococcus hemolyticus* is almost constantly found. This focus is one source of these organisms in the throat and adjacent structures. This fact must be considered in making throat cultures and in a study of the problem of hemolytic streptococcus carriers.

TWO UNUSUAL CASES OF PYELONEPHRITIS

PAUL W. ASCHNER, M.D.

NEW YORK

There is considerable divergence of opinion as to the surgical indication in cases of unilateral pyelonephritis. Recently the pendulum of opinion has swung toward conservation of the diseased kidney, decapsulation and nephrotomy being advocated as the procedures of choice. Some have taken a middle ground and are guided by the bacteriology of the urine obtained from the involved organ by means of the ureteral catheter. They choose nephrotomy for bacillary infections (such as *B. coli* and *B. pyocyaneus*), and reserve nephrectomy for coccus infections (such as staphylococci and streptococci). If it is remembered that in any infection the reaction of the human organism to the invading bacteria has an importance at least equal to that of the type of micro-organism, it follows that no hard and fast rule of this kind is to be relied on.

The decision must be made, rather, on the basis of the patient's clinical condition, on the estimation of his natural powers of resistance, and on the margin of safety. It is apparent from an examination of the pyelonephritic kidney with its diffusely infiltrated parenchyma and miliary foci of suppuration that the operation of decapsulation and nephrotomy cannot effectually remove or drain the infected tissues. The most it can accomplish is relief of tension and engorgement. Here the surgeon places his reliance on the patient's natural powers of resistance to bring about a resolution of the inflammation. The operation does not remove the focus, does not protect against extension and metastasis (the other kidney may become secondarily infected through the blood stream), and moreover exposes the patient to secondary hemorrhage, to recurrence of infection, and frequently to the dangers of a difficult secondary nephrectomy. A decision necessitating the weighing of these factors requires the nicest of clinical judgment. Primary nephrectomy is by far the safer procedure in patients showing evidence of severe septic absorption and of renal insufficiency with nitrogen retention, and in patients whose illness has been of long standing with resulting loss of weight and strength. In these patients, whose margin of safety is small, it is life which must be conserved first, and without delay.

With the object of illustrating these principles, two unusual cases of pyelonephritis are reported.¹

REPORT OF CASES, WITH COMMENT

CASE 1.—History.—A man, aged 53, admitted, July 20, 1919, had experienced some difficulty in starting the urinary stream for two months. Urination had been painful and frequent, especially at night. There was no hematuria. Five days before he had suffered complete retention of urine and had been catheterized every eight hours. For the last two days he had complained of nausea and vertigo, and had vomited once.

Examination.—The patient, admitted at night, was a pasty looking, anemic man with a distended bladder, and a moderately enlarged prostate. A soft catheter was readily passed by the intern: 20 ounces of turbid urine were obtained, and the catheter left *in situ*. The urine showed a trace of albumin, many leukocytes, a few red cells and granular casts. Blood chemistry showed urea nitrogen, 46.2; incoagulable nitrogen, 96.9; uric acid, 5.5, and creatinin, 1.4. There

1. From the Surgical Service of Dr. Howard Lillenthal, Mount Sinai Hospital, presented before the Section on Genito-Urinary Surgery, New York Academy of Medicine, Dec. 17, 1919.

were evidences, therefore, of nephritis and azotemia. The systolic blood pressure was 140, and the diastolic, 90. Fundus examination was negative.

Clinical Course.—Twenty-four hours after admission and the insertion of the indwelling catheter, the temperature had risen from 99 to 104 F., and the urine had become bloody so that a phenolsulphonophthalein test could not be made. The next morning, fever persisting, permanent drainage was stopped and catheterization at intervals was substituted. The patient continued a febrile course (101 to 103 F.) and complained of dysuria and frequency. At each catheterization a residual of several ounces of very purulent, foul urine was obtained. On the fifth day, the temperature was 104.4, and uremic symptoms appeared. The patient rapidly became disoriented, delirious and unmanageable, with involuntary urination and defecation, so that special nurses were required. Hot packs, colonic irrigations and diuretics were instituted. Although the output was increased by forcing fluids, the urine showed a great deal of pus, and was not improved by frequent bladder irrigations. The blood chemistry now showed (July 27) urea nitrogen, 56, and incoagulable nitrogen, 117. The phenolsulphonophthalein test showed only 15 per cent. excretion in two hours. Blood count demonstrated leukocytes, 19,000, and polymorphonuclears, 84 per cent. A blood culture was negative.

The cystoscopic examination revealed intense cystitis, marked trabeculation, enlargement of the middle lobe, and very marked enlargement of the lateral prostatic lobes projecting into the posterior urethra. Because of trigonal edema and the prostatic enlargement, ureteral catheters could be passed only for 1 cm. No indigocarmine was seen coming from either ureter during thirty-five minutes' observation.

A roentgenographic examination revealed no renal or ureteral lithiasis, but multiple fine concretions were seen in the prostate.

For a few days there was improvement, the temperature coming down to 99; but it rose again to 103, and the uremic symptoms became more marked. There had been slight tenderness in the left costovertebral angle which now became marked, and the lower pole of the left kidney became palpable. August 5, the left ureter was catheterized, purulent urine obtained, culture of which showed *B. pyocyaneus* and *Staphylococcus albus*. The ureteral catheter was left in situ and drained 30 ounces of purulent urine in twenty-four hours. The systemic symptoms progressed, nevertheless; chills and fever appeared, and the azotemia increased, the blood now showing urea nitrogen, 71; incoagulable nitrogen, 176, and creatinin, 5.3, the danger point having been reached.

August 8, cystoscopy demonstrated a clear urine from the right kidney, and I decided to explore the left kidney, as there seemed no doubt that it was the seat of an acute pyelonephritis which was endangering the life of the patient. Under gas and oxygen anesthesia the left kidney was rapidly exposed through the lumbar route. It was found enlarged to half again the normal size, congested, flea-bitten in appearance, and without gross abscess formation. In view of the very evident septic and toxic condition of the patient, a nephrectomy was performed. On sectioning the ureter, I found it bifid. The wound was closed with drainage.

The specimen showed an acute diffuse infiltration of the cortex and pyramids in a kidney with a bifid ureter and double pelvis.

Although loath to do so, I placed a permanent catheter in the bladder to avoid retention and its effects on the remaining kidney. The immediate results were striking. The temperature came down to 101 in forty-eight hours, and to normal on the sixth day. The uremic phenomena disappeared in twenty-four hours; the urinary output rose from 40 to 80 ounces a day, the fluid intake remaining the same.

Two weeks later (August 22), phenolsulphonophthalein test showed first appearance in forty minutes, and 10 per cent. excretion in two hours. Suprapubic cystostomy was performed with procain. Nine days later (August 31), the phenolsulphonophthalein appeared in twenty minutes, and 19 per cent. was excreted in two hours. Blood chemistry showed urea nitrogen, 25; incoagulable nitrogen, 60; uric acid, 1.6, and creatinin, 1.4. With gas oxygen anesthesia suprapubic

prostatectomy was performed, the adenoma with its numerous sandy concretions being readily enucleated. The suprapubic wound healed in three weeks. A phenolsulphonophthalein test, December 6, showed first appearance in ten minutes, and excretion of 42 per cent. in two hours.

The history of this case presents a number of interesting features: 1. The sudden appearance of virulent infection apparently precipitated by the indwelling catheter. 2. The presence of numerous concretions in the prostatic adenoma. 3. The infection of a kidney showing congenital anomaly. I did not allow my curiosity to tempt me to make a pyelogram of the healthy kidney. It may or may not be anomalous, and anomalous kidneys are more prone to infection than normal ones. 4. The picture of uremia produced by the unilateral pyelonephritis and its immediate disappearance after removal of the offending organ. 5. The excellent functional result, the patient now having a better phenolsulphonophthalein excretion than at any previous observation.

CASE 2.—History.—A man, aged 42, who had been ill for two years, stated that his urination had been frequent for many years, at times every half hour, and that it had been accompanied by burning. About two years before he had begun to have gastric symptoms and had lost weight. There had been fulness and nausea after meals and occasional vomiting of food eaten four or five hours previously. A gastro-enterologist made roentgenographic examinations and diagnosed the condition duodenal ulcer (the appendix had been removed seven years before). About a year before he had noticed that the urine was turbid, and he had had fever and chills for a few days. He had had several attacks since. Only twice had there been severe pain, referred to the epigastrium and back, and lasting about twenty-four hours. Since that time urination had been frequent (every one to one and one-half hours), and there had been pain at the tip of the penis. Occasionally there had been a dull ache in the right lumbar region. He had been recently under the care of a urologist who had treated him ten times with some instrument for disease of the verumontanum. While under this therapy he had been having attacks of fever and chills.

Examination.—On examination at my office the patient appeared pale and thin and had apparently lost considerable weight. The urine showed pus. There was definite tenderness in the right hypochondrium, and here a mass was felt, probably the kidney. There was no tenderness in the back. A preliminary diagnosis of right renal calculus with infection was made, and the patient referred to the hospital. He came to the hospital four days later, having been in bed with fever and chills. Here we found the same physical signs.

Cystoscopy detected no obstruction in either ureter. The left side yielded clear urine, and phenolsulphonophthalein injected intravenously appeared in nine minutes; the right side yielded a urine containing clumps of pus cells, and phenolsulphonophthalein appeared in fourteen minutes. Wassermann reaction and blood culture were negative. Bladder urine showed *B. coli*, but ureteral urine yielded no growth. Total phenolsulphonophthalein was 48 per cent. and blood chemistry was normal (urea nitrogen, 16.8; incoagulable nitrogen, 38.8; uric acid, 4.0, and creatinin, 1.4).

Roentgenoscopy of the stomach and duodenum was negative. A roentgenogram of the genito-urinary tract showed no stones in either kidney, but three shadows were seen in the right lower ureteral region. Stereoscopic plates with opaque catheter in place showed these to be extra-ureteral shadows. A pyelogram made with 15 per cent. sodium bromid as the opaque substance showed an enlarged pelvis and calices, but no irregularity in form.

Treatment and Results.—November 6, as fever persisted and as leukocytosis of 20,000 with 90 per cent. polymorphonuclears was present, it was determined to expose the right kidney. Just before operation a catheter was again passed up the right ureter and a specimen of purulent urine obtained for culture.

Under gas and oxygen anesthesia the usual lumbar incision was made, and an enlarged kidney was found high up under the diaphragm. It was readily freed and delivered, and showed under the capsule several minute areas of infiltration. The organ was congested, and softer than normal in consistency. Decapsulation was performed, the kidney split longitudinally, and a soft phosphatic stone (not seen in roentgenograms) removed from the pelvis. The cut surface of the kidney showed a few areas of infiltration in the pyramids, a specimen of which was excised for pathologic examination. Two mattress sutures of catgut were placed, one near each end of the wound to control bleeding, a dressed tube was introduced into the pelvis, two packings were placed in the perirenal space, and the wound was closed in layers. A small tube drain was placed in the muscle layers.

The culture on the right ureteral urine collected just before operation was reported "anhemolytic streptococcus." This was somewhat of a surprise, as the bladder urine had shown *B. coli*. If I had known this finding at the time of operation, I should have been induced to perform a nephrectomy at once. The section removed from the cut kidney surface showed purulent infiltration.

After operation there was little change in the clinical picture, the temperature reaching 103 F. in the afternoons. On the fourth day, the patient became drowsy and apathetic, was almost constantly nauseated, and the next day began to vomit small amounts of yellowish fluid at frequent intervals. Blood chemistry now showed urea nitrogen, 65; incoagulable nitrogen, 98; uric acid, 5.0, and creatinin, 2.4.

In view of the progressing evidences of sepsis and uremia, it was decided to perform a secondary nephrectomy on the seventh day. November 13, under gas and oxygen, the wound was opened and considerable pus found in the muscle layers. The kidney, which was easily freed and delivered, showed several large areas of purulent infiltration and infarction. It was quickly removed, and the wound loosely packed with gauze. The operation was completed in twenty minutes.

There was another chill after operation, and the patient's condition was poor. The vomiting which was present before nephrectomy increased in frequency and amount and was not relieved by lavage or change in position. The vomitus was thin and yellowish brown. The abdomen was distended, but soft throughout. The picture was that of an acute post-operative gastric dilatation; at least, so we thought.

On the second day, the wound was dressed and found dry and clean. A transfusion of 400 c.c. of blood was made by the Unger method. The symptoms continued, however, the temperature rose to 105, and death occurred on the third day after nephrectomy.

Examination of the wound, which was wide open, revealed a small amount of serosanguineous fluid exuding from it. The wound was free of blood and there was no communication between the perinephric space and the peritoneal cavity. When the peritoneum was opened, greenish yellow pus was found among the intestinal coils and especially in the pelvis. The left kidney was normal except for cloudy swelling. The culture of the pus showed anhemolytic streptococci and colon bacilli.

I was present at the examination and saw a layer of fat and granulation tissue between the perinephric space and the peritoneal cavity. In the peritoneal cavity were no omental or other adhesions. Most of the pus was in the pelvic pouch. As there was no evidence of any peritoneal injury, it would appear that the peritonitis was either metastatic or that it had occurred by extension. Of the two possibilities, the metastatic origin appears more likely. I believe that the vomiting which set in on the fourth day after nephrotomy marked the onset of the peritonitis—in other words, the peritonitis was already present when the nephrectomy was performed. My belief is that a primary nephrectomy would have saved this man as it did the first patient.

103 East Eighty-Fourth Street.

Clinical Notes, Suggestions, and New Instruments

TRANSPPOSITION OF VISCERA WITH MULTIPLE MALFORMATIONS

W. B. TOY, M.D., AND A. G. ELLIS, M.S., M.D., BANGKOK, SIAM.

Transposition of viscera, partial or complete, is an uncommon but not a rare condition. Malformation of organs, especially of the heart and its great vessels, is still more often found. An unusual combination of the two in an infant from the obstetric department of the Siriraj Hospital, Bangkok, appears worthy of record.

REPORT OF CASE

Clinical History.—Nang Nien, a Siamese woman, aged 27, came to the hospital for her third confinement. The personal histories of the patient and her husband were negative. Her two previous labors had been normal. The first child died at 3 years from chronic diarrhea; the second was still living. Physical examination of the woman gave no evidence of disease. The child was in the left occipito-anterior position, and no abnormal symptoms occurred during pregnancy. Labor came on at full term and was quite easy, lasting three hours. The child was of good size, well formed and well nourished, and was apparently normal. Respiration began spontaneously, but cyanosis developed. This condition increased in intensity until death, which occurred five hours after birth, apparently from heart failure.

Postmortem Findings.—The subject was a boy in whom cyanosis, especially of the head and trunk, was pronounced.

Abdomen: The position of the abdominal organs was largely the reverse of normal. The colon occupied the left side. The rectum and sigmoid were distended by meconium, the sigmoid forming a loop that extended to the right of the midline just above the pelvis, but which was chiefly on the left side. The cecum and caecum coli were slightly below and to the right of the splenic flexure of the colon; they lay anterior to the other structures, with the appendix projecting downward. The segment of the colon corresponding to the ascending and transverse portions was coiled posterior to the cecum, between the midline and the splenic flexure.

The liver was large, occupying the entire width of the abdomen, the parts on each side of the median line of the body being approximately the same in size and shape. The fissure for the umbilical vein and the quadrate and spigelian lobes were to the left of the midline of the organ; the gallbladder was to the right. Conditions as a whole would not warrant the assertion that the liver was on the left side of the body, although a further suggestive point was that the suprarenal on the left side resembled the right in shape and was adherent to the under surface of the liver.

The stomach was on the right side, where it occupied the same relative position as it normally does on the left.

No trace of a spleen could be found.

Thorax: The thymus gland was a short, thick organ, approximately 5 cm. long, 6 cm. broad, and 1 cm. thick. The left was slightly the larger of the two lobes. The pericardium and heart were on the right side to the same degree that those structures are normally on the left.

The heart appeared of the usual size. The sides were reversed, the inferior and superior cavae emptying into the auricle on the left, the pulmonary veins into the auricle on the right side. One large vessel emerged from the base of the ventricles and continued as the aorta. It had the usual three branches from the arch and a normal right bronchial artery. Through a small incision made into each ventricle near the apex, a probe passed from each cavity into the aorta. Through an opening in the interventricular septum apparently 1 cm. in diameter, the probe could be passed from one ventricle to the other. A pulmonary artery was not present.

The right pleura contained 100 c.c., the left 40 c.c. of serum. A decision as to transposition of the lungs was impossible.

because each had four lobes of the same relative size. The lung on the right side was slightly smaller, but the difference might very well have been due to the greater amount of pleural fluid on that side. Both lungs were expanded throughout.

As it was considered desirable to preserve the entire body as a specimen of transposition, the heart was not further opened, and only the liver was removed in order to expose the stomach. No other abnormalities were noted.

Anatomic Diagnosis.—Transposition of viscera; absence of pulmonary artery; patent interventricular septum; four-lobed lung each side; absence of spleen; bilateral hydrothorax; cyanosis.

COMMENT

Of the conditions present in this child, the rarest is absence of the pulmonary artery. As literature on the subject is not available, we report the case without statistics.

PULMONARY ANTHRAX: REPORT OF A CASE

W. R. BROOKSHER, JR., M.D., AND J. A. BRIGGS, BINGHAMTON, N. Y.

Intern, City Hospital, and Pathologist, Kilmer Memorial Laboratory, respectively.

It is believed that the rarity of true pulmonary anthrax warrants the report of the following case.

REPORT OF CASE

History.—M. P., a Pole, aged 36, a worker in the tannery of a local shoe manufacturing concern, was recommended from the factory dispensary to the service of Dr. D. C. O'Neil, through whose courtesy the case is reported. The tentative diagnosis was bronchopneumonia. A complete history was not obtainable, but the salient feature was that the patient had been suffering for one week previously with a sore throat and a pain across the right chest. It was discovered that the patient had been handling "green" hides in the tannery for some time before the onset of symptoms, but the exact period was not ascertained. There had been no treatment of any sort, and the patient was sent to the hospital from the dispensary immediately after examination.

Physical Examination.—The patient was well developed and well nourished and apparently in good physical condition. The skin was moist and relaxed, with no visible lesions of any kind; a moderate cyanosis was observed in the buccal mucous membrane and at the finger tips; there was no irregularity of the pulse rate, the volume and tension being about normal, the sphygmomanometer reading was: systolic, 118; diastolic, 78; the radial arteries were readily compressible and not thickened; respiration was most difficult, and it was this dyspnea which first attracted attention to the possible seriousness of the attack. Ordinary examination of the throat and pharynx revealed no pathologic condition other than a slight congestion of the mucous membrane. Smears were not taken. A thorough examination of the chest presented no evidences of a pneumonitis—there was no dulness, no increase of fremitus, nor any discoverable abnormalities other than numerous coarse, moist râles over the entire surface of both lungs. There was no apparent cardiac involvement, hypertrophy was not evident, and the valvular sounds were clear and distinct. There was no distention or rigidity of the abdomen, and no points of tenderness were found. The extremities were normal. Bowel evacuations had been regular, and there had been no urinary disturbances. Prolonged coughing spells, productive of considerable pinkish, frothy mucus, seemed by their intensity to annoy the patient more than the more evident dyspnea. The diagnosis depended, therefore, more on the notation of the subjective, rather than by elicitation of any objective, signs.

Clinical Course.—On admission, the temperature was 101.3 F., pulse rate 92, and respiration rate 20. General treatment was instituted, embodying heat to the affected side of the chest, a mild mercurous chlorid series followed by oleum ricini, with the administration every four hours of 2 grains of caffein sodiobenzoate and 10 grains of potassium citrate.

During the night it was noted that the patient perspired freely with a rise of the temperature to 103.2, the pulse and respiration rate being 102 and 32, respectively. On the following day the patient appeared fairly comfortable except for some slight nausea with emesis in the early afternoon. In the evening, the cyanosis and dyspnea were noticeably greater, and on account of the fact that anthrax bacilli had been detected in the sputum, the patient was transferred to an isolation ward and 50 c.c. of antianthrax serum were given intravenously, supplemented by hypodermic injections of $\frac{1}{400}$ grain of atropin sulphate with 10 minims of epinephrin (adrenalin) chlorid (1:1,000 solution) every three hours. The expectoration became more profuse, and gross blood was apparent. The patient slept well during the night, took his nourishment well, and showed no untoward effects of the serum. There was, in fact, an appreciable improvement, respiration became less laborious and the cyanosis was less marked. During the following day, the orthopnea, previously slight, became exaggerated, the respirations were increased to 40 per minute, and the pulse rate rose to 118, while the temperature dropped to a normal level. In the early morning of the fourth day in the hospital, the respirations were even more labored and the pain in the right chest was reported as more severe. Cyanosis increased, the extremities became cold, the temperature reached 97, and the pulse was weak and irregular with a rate of 128. Although vigorous stimulation was resorted to, the patient died; necropsy was refused.

Laboratory Findings.—Routine urinalysis on admission was negative and the blood count revealed 15,000 leukocytes, the increase being principally of polymorphonuclear neutrophils.

Temperature, pulse and respiration ratio (four hour intervals): solid line, temperature; broken line, pulse; dotted line, respiration.

A count made two days later gave 20,200 leukocytes, with the same relative differential. On admission the sputum was typed for pneumonia, and it was then that many large, nonmotile, gram-positive bacilli, morphologically resembling the anthrax bacillus, were discovered. To confirm or deny the suspicion, a blood culture was taken, the culture medium being glucose agar. Colonies were numerous at the end of twenty-four hours and the same bacillus was found in pure culture. A suspension was injected intraperitoneally into a guinea-pig and a rat; the pig succumbing in twenty-four hours and the rat twelve hours later. On necropsy of the animals there was noted the characteristic enlargement of the spleen, with distended capsule and with softened, dark and congested stroma; the liver and kidneys showed the same changes; the lungs were edematous; the peritoneal fluid was slightly blood-tinged; in the pig, hematuria was an additional symptom. From the blood of each animal the organism was recovered in great numbers, and sections of the two spleens showed the organism distributed throughout, surrounded by areas of minute hemorrhages. The forty-eight hour agar culture showed the typical tuft hair appearance of the colonies under the low magnification. In gelatin stab culture, the growth proceeded as in spicules diverging from the uppermost portion of the stab, and after forty-eight hours the gelatin about the top of the stab became liquefied. The growth in broth was evidently rapid, but the bacilli showed a tendency to sink, leaving clear broth at the top. In all smears made from culture mediums, spore formation was readily demonstrated by contrast staining, while the capsule was especially well defined in the smears made from the blood of the infected pig and rat by the Romanowsky blood stain. Hemolysis was noted in the blood

plates. The continuance of sputum typing proved the presence of a pneumococcus of Type IV, although the sputum was contaminated by numerous staphylococci and streptococci. A corroborative second sputum examination and blood culture from specimens taken the morning before death yielded essentially the same results.

CONCLUSIONS

1. Pulmonary anthrax infection can be diagnosed only on positive laboratory findings; sputum examinations and blood cultures are the means employed.
2. Early diagnosis is essential, and it would seem that vigorous treatment by intravenous administration of anti-anthrax serum offers the only hope of recovery.
3. Pulmonary anthrax may appear without the evidences of a violent pneumonia and yet prove fatal as a result of a decided clinical toxemia.

AND OTHER REMEDIES IN THE TREATMENT OF DISEASE.

USE AND ABUSE OF CATHARTICS*

(Continued from page 249)

PURGATIVE PILLS

Purgative pills are among the "best sellers" in drug stores. This popularity attests to at least some measure of merit; and it must be admitted that pills are a simple, convenient, inoffensive and economical means for obtaining cathartic action. However, these very advantages also contribute to their great abuse, and cause them to lead all other purgatives as creators of the cathartic habit. Because of this, as well as because exact adjustment of dose by the physician and its gradual reduction by the patient are not as readily accomplished with pills as with other administration forms, prescriptions for purgative pills should not be given to patients unless there are positive indications for them. The triad of the careless routinistic doctor, the ignorantly "counter-prescribing" druggist, and the blatantly advertising proprietary pill promoter is responsible for having made a large number of persons "colonic" cripples — life-long slaves to pills.

INDICATIONS

Purgative pills are convenient for occasionally stimulating bowel evacuation in bed patients. There can hardly be an objection to such employment. But the habitual use of pills is justifiable only when the patient's constipation is hopeless so far as cure is concerned. This condition may exist in the toothless aged, who cannot or will not use artificial dentures, and who, therefore, do not eat enough coarse food to stimulate the bowel to proper function. It also exists in the multiparous woman, who has sacrificed the integrity of her abdominal muscles to her progeny and who, by reason of insufficiency of abdominal pressure, demands an increase in the motor activity of her intestinal musculature, which, unaided, is not equal to the task.

Sedentary habit, on the other hand, is no justification for purgative pill enslavement, unless heart dis-

ease or other physical defect renders a sufficiency of muscular exercise impossible. The attempt to purchase freedom from some of the ills of sluggish habits of life by the habitual use of "liver" pills should be depreciated; other important organs besides the bowel functionate below par in the sedentary person.

When it is a question of the use of the crutch or not walking at all, we choose the crutch as the lesser of the two evils — and so it is with purgative pills. In case chronic use becomes a necessity, pills are superior to all other administration forms of cathartics, chiefly on account of their convenience.

PILL ECONOMY

To minimize as much as possible the use of purgative pills, patients should be directed to use a pill at the end of any day on which they have not had bowel evacuation. The patient will then not take the pills oftener than once every other day; and, not as often, should a spontaneous tendency to bowel movement manifest itself. Thus the patient will have a thorough bowel evacuation at least every other day.

The important thing is to fit the patient as exactly as possible with the agent or agents best suited for him and in the smallest dose required by him. There is no sense in prescribing too mild a pill, and having two or three of these taken for an indefinite time, when one pill of exactly the required strength might as well be prepared. This is one of the chief objections to ready-made pills, even though they be official.

PRINCIPLES OF PILLS CONSTRUCTION

While *curare cito, tuto et jucunde* is our aim, simple prescriptions must be preferred to complex prescriptions, provided they produce as good results. The more complex the remedy, the more unmanageable and liable to unforeseen complications does it become. Nowhere is the principle of simplicity in prescribing more sinned against than in connection with cathartic pills.

The two chief reasons for combination are: mutual reinforcement, and the antagonizing of undesirable side effects. Mutual reinforcement is best obtained by what might be called "*heterotopic synergism*," i. e., the cooperation of agents affecting different functional subdivisions of the organ to be acted on, whereby a result may be obtained with smaller dosage of each of the ingredients than if they were employed uncombined.

FUTILITY OF THE A. S. B. COMBINATION

A good example of an attempt at "rational" combination for both these effects is the "A. S. and B." pills (Pills of Aloin, Strychnin and Belladonna, N. F.).

Nothing may seem more logical than to add to the aloin some strychnin for the purpose of increasing the irritability of the motor neurons on which the aloin is to act; nor might it seem that anything would be more suitable to counteract the reputed tendency of aloes to produce griping than the powerful antispasmodic, belladonna. Unfortunately, by utilizing them in pill form at the same time, they cannot possibly act together, because of the different speed and duration of action of the three agents. Aloin is slow in action, requiring from ten to twelve hours — that is why it is generally given at bedtime. Strychnin and atropin, on the other hand, are rapidly absorbed and rapidly excreted, having but a brief duration of action. No experienced clinician would expect either of these

* This is the sixteenth of a series of articles on the pharmacology, physiology and practical application of the common laxatives and cathartics. The first article appeared October 18.

alkaloids to act for more than four hours. By the time the aloin gets its action in, the alkaloids have long since left the system by excretion into the urine.

To put these theoretical considerations to the experimental test, more than thirty volunteers in a class of medical students were given two pills each to be taken with an interval of about a week. One of these contained aloin; the other, the same dose of aloin and some extract of belladonna in the quantities found in the A. S. and B. pills. Strychnin was omitted, to reduce the experiment to its simplest terms. The pills were called No. 1 and No. 2 pills, and the experimenters did not know which of these contained the belladonna. They were asked to distinguish its presence by difference of action. The majority could not notice any difference whatever; a few thought the belladonna-containing pills were the ones that produced more griping; a few, that the simple aloin pill acted more disagreeably. Clinical use of the official *Pills of Aloes*, containing 0.13 gm. (2 grains) each of aloes and of soap, as compared with similarly extensive use of the A. S. and B. pills, did not demonstrate any greater tendency to griping displayed by the one than the other.

Admitting that the number of observations in the experiment just noted is too small for positive deductions—it ought to be repeated over and over again and would be quite as instructive as some of the animal experiments performed by medical students—the results, as they stand, support the theoretical deductions based on the relative time of action of the ingredients. After all, griping is a matter of size of dose, sensitiveness of individual, and condition of enteric contents rather than of name of drug.

It is gratifying, therefore, that the *Compound Laxative Pills* (U. S. P. VIII) similar in composition to the A. S. and B. pill, with the no doubt uncalled-for addition of ipecac, were deleted from the present pharmacopeia. However, these pills as well as the *Compound Pills of Aloin, Strychnin and Belladonna*, N. F., containing some extract of cascara, in addition, are still extensively used.

Rather popular at the present time also are the unofficial "*Cascara Compound Pills*," commonly called "Hinckle's Pills," each containing:

Cascara	Grain
Aloin	$\frac{1}{4}$
Resin of podophyllum	$\frac{1}{4}$
Extract of belladonna	$\frac{1}{16}$
Strychnin sulphate	$\frac{1}{160}$ – $\frac{1}{120}$
Oleoresin of ginger	$\frac{1}{8}$

One wonders whether they are popular because their formula is not contained in the U. S. P. and N. F.—it has been said facetiously that the best way to destroy the popularity of a preparation is to make it official. Efficiency is, of course, granted to these as well as to all the other aloes pills, no matter what their composition. The question is as to the desirability of such ridiculous polypharmacy.

OBJECTIONS TO COMPOUND CATHARTIC PILLS

The official compound cathartic pills are no less objectionable. The chief objection is that they contain a considerable amount of calomel, and that people may buy them freely in drug stores and use them indefinitely, not knowing that they are poisonous. Every now and then cases of calomel poisoning can be traced to the compound cathartic pills, taken by some misguided layman for the benefit of his "liver." In drug stores the desirable custom existed quite generally of dispensing the *Vegetable Cathartic Pills* of the National Formulary—also known as "Compound Cathartic Pills, Improved"—when people called for

compound cathartic pills without a prescription.¹ The "improvement" consists in the substitution of podophyllum and leptandra for the calomel and gamboge, and in the addition of extract of hyoscyamus and oil of peppermint, so that the "improved" pills boast of ten different ingredients: aloes, extract of colocynth, cardamom seed, resin of scammony, soap, extract of hyoscyamus, resin of jalap, extract of leptandra, resin of podophyllum and oil of peppermint. Eight ingredients are far too many to meet the demands of scientific combination, namely, that each ingredient improve the action in a demonstrable manner. No one, so far as is known, has even attempted to render this demonstration for either of these pills; and while some of the ingredients might conceivably reinforce each other, that which has not been demonstrated has no existence in science. In this demonstration, aloes and each of the other ingredients would have to be compared when given separately and when combined with each other in all possible different variations. This would require, with eight ingredients, more than fifty different sets of experiments, each of which should probably include from fifty to 100 observations. Until such a demonstration proves otherwise, these combinations must be considered utterly unscientific.

(To be continued)

1. These "improved" pills were deleted from the pharmacopeia at its last revision. It is to be regretted that the others did not meet the same fate, for they are even more objectionable.

Treatment of Malaria.—The subcommittee on medical research of the National Malaria Committee consisting of Drs. Charles C. Bass, New Orleans; William Krauss, Memphis, Tenn.; William H. Deaderick, Hot Springs, Ark.; George Dock, St. Louis, and Charles F. Craig, Col., M. C., U. S. Army, presents the following as a standard method of treatment of malaria for the purpose of curing the patient of his infection and recommends its general use by the medical profession. It is believed that this treatment will, in the great majority of cases, prevent relapses in the patients themselves and also prevent transmission of the infection to others. This opinion is based largely on the results of the treatment by this method, under average conditions, in the homes, of a large number of persons infected with malaria. For the acute attack, 10 grains of quinin sulphate by mouth, three times a day, for a period of at least three or four days, to be followed by 10 grains every night before retiring for a period of eight weeks. For infected persons not having acute symptoms at the time, only the eight weeks' treatment is required. The proportionate doses for children are: under 1 year, $\frac{1}{2}$ grain; 1 year, 1 grain; 2 years, 2 grains; 3 and 4 years, 3 grains; 5, 6 and 7 years, 4 grains; 8, 9 and 10 years, 6 grains; 11, 12, 13 and 14 years, 8 grains; 15 years or older, 10 grains. It is not claimed that this is perfect or even the best treatment in all cases, but it is our belief that it is a good and satisfactory method for practical use to prevent relapse and transmission of the infection to other people. In a circular letter from Senior Surgeon Henry R. Carter, U. S. P. H. S., secretary of the National Malaria Committee to health officers of states in which malaria prevails the belief is expressed by the committee that a general adoption of this method of treatment by the physicians who treat malaria will result in freeing a large number of malaria patients from infection, so that they will neither themselves suffer from relapses (of infections incompletely cured), nor be sources of infection to mosquitoes and thus to other people. This would result in a very great diminution of malaria throughout the country. If this treatment meets with approval, it is suggested that it be brought to the notice of physicians in the malarious sections of the various states and that such other measures be taken as may be feasible for its general adoption.

THE DEBATED THEORIES OF SUPRARENAL FUNCTION

In a series of contributions published in recent years from the Laboratory of Physiology in the Harvard Medical School, Cannon and his co-workers have developed certain hypotheses with respect to the functions of the suprarenal glands. They have submitted experimental evidence that the suprarenal medulla is stimulated to secrete by emotional excitement, pain and asphyxia—conditions known to be accompanied by activity on the part of the sympathetic nervous system. In natural existence, Cannon argues, these conditions would commonly be associated with more or less struggle; and the visceral changes, including suprarenal secretion, which were said to accompany the emotional states, would be useful in great muscular effort. Both the sympathetic system and the suprarenal medulla were thus interpreted to play a part in important bodily adjustments.¹ This was quite different from the view that the suprarenal acts to detoxicate harmful products in the body, or the assumption that secreted epinephrin is destined to lend tonus to certain bodily structures. Cannon has designated his view of the association between suprarenal activity and the function of the sympathetic division of the autonomic nervous system in bodily emergencies as the "emergency theory."

Cannon's views have met with criticism from several sources. In this country, Stewart and Rogoff at the Western Reserve University have insisted that there is no increase of suprarenal secretion in the emotional excitement represented by fear, rage and pain, or in asphyxia. In France, Gley and Quinquaud also have denied that a true epinephrinemia exists. Unless it can be demonstrated that there is actually an augmented suprarenal secretion in the conditions postulated, the emergency theory fails.

More recently, Cannon² has subjected the work of his opponents to a severe criticism, besides adding new evidence for the tenability of his earlier contentions.

Heretofore, epinephrin has as a rule been tested for in blood removed from the body. It has been found, however, that when the heart is completely denervated it becomes an organ highly sensitive to epinephrin, and hence can be employed to demonstrate an increment of suprarenal secretion in the circulating blood. The denervation is accomplished by severance of the vagus nerves and removal of the stellate ganglions in experimental animals. By the use of this procedure, which seems to avoid the defects charged to the older more clumsy methods of blood removal and testing, Cannon has duplicated his earlier findings.

For the present, therefore, it would seem that the burden of proof is again thrown on the shoulders of those who deny the tenability of Cannon's emergency hypothesis. The statement made in *THE JOURNAL*³ that suprarenal secretion is not a necessity, at least under ordinary conditions of existence, still seems to be valid. As Cannon remarks, thus far no reliable evidence has been brought out by any investigator that there is any secretion whatever of the suprarenal glands under quiet, peaceful conditions. He does contend, however, that in times of great emotional stress or under circumstances which cause pain or asphyxia, epinephrin is secreted. This has been the foremost item under debate. Epinephrin is regarded as an aid, not a physiologic essential. Excitement, pain or asphyxia are, in natural existence, commonly associated with violent struggle for self-preservation. Under such circumstances, says Cannon further, the operation of the sympathetic division of the autonomic system, together with the aid which epinephrin affords, will muster the resources of the organism in such a way as to be of greatest service to such organs as are absolutely essential for combat, flight or pursuit. He concludes that the emergency theory of the suprarenal medulla is the only one which thus far has any experimental support.

AN INTERPRETATION OF THE CREATINURIA OF INFANCY

Normally, the urine of the adult male never contains creatin, although the closely related substance creatinin is a never-failing component of the urine as well as of the blood. Healthy women excrete creatin at times.⁴ Infants and children, on the other hand, exhibit a creatinuria regularly on normal diets and under normal conditions of health. The reason for this peculiarity of metabolism in the adolescent period has never been discovered, although various hypotheses have been advanced in explanation. Thus it has been suggested that creatinuria is associated with acidosis. These two phenomena doubtless are concurrent at times; yet this fact does not demonstrate a causal rela-

tion between them. It would be difficult to imagine that the acid-base equilibrium, on the upset of which a true acidosis in the body depends, should be so continuously disturbed as the normal continued output of urinary creatin in childhood would demand. There is no justification in assuming for the early period of life a continuous depletion of the fixed alkali of the blood, such as the modern definition of acidosis would demand. The carefully conducted investigations of this subject recently undertaken by Gamble and Goldschmidt⁵ at Johns Hopkins University show, furthermore, that variations in the acid-base intake have no effect on the creatinuria of infants. We conclude with these investigators, therefore, that there is today no satisfactory evidence that acidosis per se is a factor in the production of creatinuria.

When creatin is fed to adult man it may not reappear in the urine unless the amount introduced is a considerable one. Ingested creatinin is excreted again almost quantitatively; at any rate, it can be recovered or accounted for to a far greater extent than can ingested creatin. It may be, therefore, that the adult can utilize or assimilate creatin, although this is not true of creatinin. In the infant or adolescent child, however, the fate of ingested creatin seems to be better established. According to the latest evidence,⁵ small amounts even of ingested creatin lead to an increase of the creatinuria of infants. When a diet rich in protein is given, the elimination of the ingested creatin may be practically complete. This fact has an important bearing on another hypothesis regarding the genesis of creatinuria which relates the phenomenon to the size of the protein intake. It has been observed that wide differences exist in the output of creatin by infants when the excretion on high and low protein diets is compared. Thus, Denis and Kramer⁶ of the Massachusetts General Hospital have asserted that the amount of creatin found in the urine of children is directly dependent on the intake of protein, being high when large quantities of protein (creatin-free) are ingested, and decreasing and in some cases disappearing entirely when the child is fed a diet of an extremely low protein content.

Gamble and Goldschmidt⁷ have called attention to the fact that experiments on high and low protein diets in infancy have usually involved feeding larger or smaller quantities of milk. Until lately the existence of creatin and creatinin in this secretion has generally been overlooked.⁸ The new experiments of Gamble and Goldschmidt indicate that whereas the creatin excretion of infants bears a relation to the quantity of

milk fed, this concerns the nonprotein rather than the protein constituents of the secretion. Pending further investigation of the subject, it seems logical to assume that as milk, the customary staple food of infancy, contains creatin; and as this substance, for some as yet unknown reason, is not destroyed readily in the adolescent organism, the ingestion of creatin is a large factor in the creatinuria of infancy. Whether the dietary intake of creatin is sufficient to account so well for the creatin excreted in the urine in other periods of growth remains to be ascertained by further research.

THE DEATH OF TISSUES AND THE LIFE OF PROTOPLASM.

Until a few years ago, it was assumed that the life and development of tissues and their constituent cells are bound up with the body as a whole. Body cells had not been "cultivated" in vitro in the way that has become familiar in the growth of micro-organisms of various sorts. The pioneer experiments of Harrison¹ showed the possibility of cultivating tissues outside of the body by the demonstration that embryonic tissue of the frog, transplanted into coagulable lymph, will develop normally. Subsequently Carrel and Burrows² succeeded in cultivating outside of the body adult tissues of mammals. These possibilities have since been demonstrated repeatedly by various investigators in different parts of the world. Not only normal but also malignant tissues have thus been grown in culture.

At first, before the experimental technic was developed to its present stage of perfection, the life of the tissue cultures outside of the body was brief. It was measured in days or weeks. When Carrel³ announced, in 1912, that fragments of connective tissue had been kept in vitro in a condition of active life for more than two months, the problem of senility and death were put in a new light. Are they preventable occurrences due to the accumulation of waste or the lack of nutrient or some other remediable or avoidable factor? As Carrel remarked in connection with these earlier observations, it is conceivable that the length of life of a tissue outside of the organism could greatly exceed its normal duration in the body, because elemental death might be postponed indefinitely by a proper artificial nutrition.

Colonies of infusoria like bacteria proliferate indefinitely. Woodruff has shown that the protoplasm of paramecia is capable of seemingly endless reproduction, without the sexual device of "renewal of youth" by conjugation. Likewise, the connective tissue cells now appear to have the power of multiplying indefinitely in a culture medium, as do micro-organisms. A strain of

connective tissue cells first cultivated by Carrel in 1912 at the Rockefeller Institute of Medical Research, New York, is still very active after more than seven years of life outside the body in vitro.⁴ Its rate of activity has not decreased during this period, despite more than a thousand transplantations that fragments of it have undergone. Such facts place the regenerative capacities of protoplasm in a new light; they likewise lend further interest to the broader problems of tissue culture and conservation, and bring us measurably nearer to the possibilities of controlling or modifying tissue growth by understanding its laws.

Current Comment

"INFLUENZA"

Presumably, the recent recrudescence of influenza in several of our larger cities, including Chicago, Baltimore and New York, has had something to do with the Congressional action appropriating a half million dollars to control influenza.⁵ The devastation caused by the great epidemic of a year ago, while still fresh in the minds of many, was, nevertheless, already beginning to be forgotten especially by those whose homes were untouched by the disease. Fortunately, there is reason to believe that the present prevailing sickness in most instances does not approach either in extent or in virulence the violent infections of last year's epidemic. The percentage of deaths is considerably lower and the number of persons affected probably far below the number affected at that time. Further, the distinction between the serious condition occurring during the last epidemic and milder infections, such as common colds, grip, tonsillitis, sinusitis, rhinitis and coryza, is not absolutely clear. During an epidemic it is too easy and convenient to refer to all such conditions as that which the epidemic concerns. As has been repeatedly stated, local flare-ups of such sequelae were common following previous epidemics. Many physicians have written regarding preventive and therapeutic measures, evidently under the impression that some specific methods may have been worked out. It is doubtful whether such measures exist and also whether they will be discovered in time to demonstrate their virtues in connection with the present conditions. This is especially true when we consider that the bacteriology of these infections varies in different parts of the country and that different persons react in different ways to different bacteria. Health authorities, physicians and the public should not, therefore, "view with alarm" the present morbidity. Perhaps when the excitement of the hour has passed and the statistics are collated, they will reveal that the death rate from pneumonia of this year is not much greater than it was in winters previous to the great epidemic. In the presence of illness the physician and patient will do well to rely on the ordinary preventive measures against acute infections, on good hygienic care and time-tried

symptomatic treatment. Particularly important is early rest in bed; moreover, the patient should remain in bed until well after the symptoms have disappeared and the temperature returned to normal.

COMPETITORS IN UNPOPULARITY

The physician is not the only scientific man who is made the sport of the pseudo-scientist or the disappointed layman. The *Scientific American*, under the heading "Our Unpopular Weather Man," draws a pertinent comparison in an editorial that is so good that we quote it in full:

Who, in all history, ever suffered unpopularity more widespread and more undeserved than the weather man? When his prophecies hit the mark, this is taken as a matter of course, and tomorrow will forget today's success. But his occasional failures—especially if rain comes when he had given his sanction to our plans for an outing—such impardonable failures are recorded in indelible writing, with illuminated capitals to impress the event on the memory.

And, strangely enough, in this atmosphere of unforgiving criticism, the charlatan weather prophet still flourishes, and with blatant self-confidence foretells to a congregation of believers the weather for each and every day next year or the year after, or any other year. Old myths, negated anew by each year's experience, seem to have a charmed life, proof against the bullets of obvious fact. The scientific weather man, in modesty, forbears to predict anything but the immediate future—tomorrow, and perhaps the day after. Beyond this lies uncertainty. He hopes, indeed, for a future development of his science when, aided by more complete equipment, he may be able to give at least an approximate indication of more remote events. As yet, however, this is but a pious hope.

But the charlatan is not encumbered with any such impediments of modesty. It is just as easy to foretell the weather a hundred years ahead as a hundred hours or minutes—it is even easier, for there will be none to call you to account if you miss the mark.

In this the popular attitude is much the same as in the matter of medical attention. The doctor's successes are soon forgotten; his inevitable failures—for the foe is in the end invincible—are burnt into the memory. And those who are most vociferous in their criticism of the bona fide physician faithfully plying his science, are commonly the first to turn to the charlatan for aid in the time of trouble. Truly, they receive their reward.

The harm done is perhaps not so very great. The physician goes on his rounds regardless of undeserved fault-finding; and the weather man continues to publish his bulletin day by day, undisturbed by criticism.

Yet our sense of justice impels us to plead: In mercy, good people, be charitable, and remember that the weather man only foretells, he does not make the weather.

The weather man, like the physician, deals with factors which, while as old as the universe, are still but little understood and are of bewildering complexity. It is because of this complexity that empirics in medicine and in meteorology flourish. But the quack doctor has a vast advantage over the quack weather forecaster. The charlatan weather prophet has about an even break in the chances of guessing right; the medical charlatan has many more chances of getting credit for curing the patient. For in how large a percentage of all ailments, serious and trivial combined, does the patient get well without treatment or even in spite of treatment? In one other respect the science of meteorology has an advantage over the science of medicine: there are not a thousand-and-one meteorological

4. Ebeling, A. H.: A Strain of Connective Tissue Seven Years Old. *J. Exper. Med.* 30: 531, 1919.
5. General News, this issue, p. 334.

cults each based on its own bizarre conceptions of the climatic universe, each with its following of enthusiastic ignoramuses and each convinced that scientific meteorology is a snare and a delusion and a deep-laid scheme on the part of the meteorologists to deprive a free people of their inalienable rights to have whatever kind of weather they want. No, much as we sympathize with the weather man, we still feel that he has a tremendous advantage over the medical man. The cocksureness of ignorance will, of course, command a hearing in meteorology as it does in the realm of medicine. The conservative prognostications of the scientific man never make the appeal that is carried by the blatant assurance of the quack. But science goes on the even tenor of its way and the public, when it has something serious at stake, will continue to rely on the reports of the weather bureau and the ministrations of scientific medicine.

UNIVERSAL MILITARY TRAINING

The Committee on Military Affairs of the United States Senate has recommended for passage the Wadsworth army bill and retained the clauses providing for compulsory universal military training. The vote in the committee was nine to two in favor of the bill, which probably means that the bill will pass the Senate. As amended, the bill provides for training periods of four months for each young man, to be taken between the ages of 18 and 21. Opportunity will be given twice each year, making six periods from which the young man may select. While such a brief training period as four months is by no means sufficient, the bill is to be commended, for, after the value of the training becomes appreciated, its duration will probably be extended.

THYROIDECTOMY IN PREGNANCY

It is well known that women with myxedema seldom become pregnant. As myxedema represents the highest grade of hypothyroidism, and the milder grades are not incompatible with pregnancy, anything that throws light on the effects on pregnancy of the removal of the thyroid is not without clinical interest. Many years ago, Halsted in his classical experimental work on the thyroid gland showed that in dogs from which the gland had been partly removed pregnancy might result in the birth of puppies whose thyroids were from twelve to twenty times larger than normal. No particular attention was attracted by these somewhat startling observations, although one or two later observers working on pathologic conditions of the thyroid experimentally produced have reported conflicting results. The question has recently been restudied by Ukita,¹ who performed thyroidectomy on pregnant rabbits. His two main conclusions are that the removal of the thyroid in the rabbit greatly prolongs the period of gestation, and that it produces definite developmental changes in the young. The period of gestation was in some instances twice the normal. The young resulting from these pregnancies were undersized, showed by pathologic and roentgen-

ray study delayed ossification of the bones, and also showed hypertrophy of the thyroid gland which was associated with the microscopic appearances of a degree of function more active than is normal in the newly born. These observations recall the fact that a relationship between the activity of the thyroid and sexual functions has long been recognized by clinicians. It is well known that enlargement of the gland frequently takes place during menstrual periods, and commonly takes place during pregnancy. The relationship of the thyroid to physical and mental development as exemplified by sporadic and endemic cretinism is also a thoroughly authenticated clinical fact. The experimental observations of Ukita would seem to be particularly suggestive in their bearing on the possible relationships between the milder grades of hypothyroidism and hyperthyroidism in women, and the development of children born of such mothers. They suggest that the function of the thyroid gland may exert some influence on the duration of pregnancy. Is it possible that some cases of delayed birth are due to hypothyroidism in the mother? May premature delivery be associated with the milder grades of hyperthyroidism? Investigations along these lines should prove interesting.

EFFECT OF WAR ON GROWTH OF CHILDREN IN DIFFERENT SOCIAL GROUPS

It is an old adage that "death is no respecter of persons"; perhaps it may be said in analogous sense that war is no respecter of classes. High and low, rich and poor—all social groups have suffered from its ravages, often in unexpected ways. In many respects, war tends to bring humanity nearer to a common level. An interesting illustration has lately been published by the Munich pediatrician Pfaundler¹ regarding the effect of war conditions on the growth of children. During prewar days, in the measurements of adolescents of school age, differences associated with unlike social status of the parents were clearly discernible from the available statistics. Thus, as a rule the children from homes of the professional classes exhibited a noticeably larger body weight and height than those of the same age born of parents in the so-called working classes. The exigencies of the last five years—particularly the shortage of suitable foods—have affected the growth of children of school age in general in the central countries of Europe. For example, at the age of 6 years Munich girls and boys have grown on the average 3 cm. less in height and 1 kg. or more in weight than was the case in the same city before the war. The average decrease in gains is, however, more conspicuous in the children of the professional group than in those from the less well-to-do classes. Six-year old boys of the latter were only 0.2 kg. behind the prewar average for their category, whereas the other group of boys were 1 kg. lighter in weight than were their equals in age in 1914. As Pfaundler interprets this, since the children of the poor are as a rule smaller and lighter than those of the well-to-do, the war has tended to level the classes from a somatic as well as other standpoints.

Association News

THE NEW ORLEANS SESSION

To New Orleans by Boat

Dr. H. W. E. Walther, New Orleans, chairman of the Subcommittee on Transportation of the Local Committee of Arrangements for the New Orleans session, April 26 to 30, desires to assist in the getting up of boat parties to go to New Orleans. He wishes to get into communication with local medical organizations in cities located in the Mississippi River Valley as well as in seaport cities on the Gulf of Mexico and the Atlantic Coast. He offers his services in order that organizations may be effected at different points of parties of sufficient numbers to justify chartering boats for the trip. Whenever such groups can be assembled, efforts will be made to induce steamship companies to arrange for these excursions. Letters to Dr. Walther should be addressed to the Headquarters of the Local Committee on Arrangements, 1216 Maison Blanche Building, New Orleans, La.

From Baltimore to New Orleans

Dr. Ira J. Haynes, P. O. Box 24, Richmond, Va., is interested in arranging a party to go by boat from Baltimore to New Orleans. The itinerary under consideration contemplates touching at Old Point Comfort, Va., Charleston, S. C., and a twelve-hour stopover in Havana, the boat being scheduled to arrive in New Orleans early on Monday, April 26, in time for the opening meeting of the House of Delegates.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

COLORADO

Personal.—Dr. Charles D. Spivak, Denver, left for New York, December 28, to join the other members of the joint distributing committee of the Jewish war sufferers relief work, and expected to sail for Europe, January 2.

Tuberculosis School Incorporated.—A number of physicians of Colorado Springs filed an affidavit, January 1, for the incorporation of the Colorado School of Tuberculosis, the purposes of which are described as follows: "To furnish without pecuniary profit to its members, opportunity for special advanced study in tuberculosis to physicians and others through the medium of regular courses of instruction and institutions, and laboratories and other agencies devoted to investigation, treatment and cure of the disease."

New Officers.—At the annual meeting of the Medical Society of the City of Denver, Dr. Arnold S. Taussig was elected president; Dr. William A. Sedwick, vice president; Minnie C. T. Love, secretary (reelected), and Dr. Franklin P. Gengenbach, treasurer (reelected), all of Denver.—El Paso County Medical Society at its annual meeting in Colorado Springs, December 10, elected Dr. Clarence R. Arnold, president; Dr. George B. Gilbert, vice president; Dr. Claude E. Richmond, secretary, and Dr. Omer R. Gillette, treasurer, all of Colorado Springs.

GEORGIA

New Laboratory for Fort McPherson.—The War Department announced, December 29, that plans and specifications for a new permanent department laboratory building to be erected at Fort McPherson, Atlanta, had been prepared.

Tributes to Service Men.—December 19, the members of the Georgia Medical Society of Chatham County who had served in the army and navy were given a supper at the Hotel DeSoto by the society.—At the annual banquet of the Fulton County Medical Society, January 8, the members of the organization who were in the military service during the war were the guests of honor. Dr. Elmore C. Thrash,

Atlanta, the retiring president, acted as toastmaster, and the president-elect, Dr. Walter B. Emery, Atlanta, delivered the principal address on the subject of loyalty.

New Officers.—At the annual meeting of the Georgia Medical Society of Chatham County, held in Savannah, December 16, Dr. William H. Myers was elected president; Dr. Lawrence Lee, vice president, and Dr. Everett L. Bishop was reelected secretary-treasurer, all of Savannah.—Walker County Medical Society, at its annual meeting held in Lafayette, elected Dr. Robert M. Coulter, president; Dr. James P. McWilliams, vice president, and Dr. John H. Hammond, secretary, all of Lafayette.—At the annual meeting of the Clarke County Medical Club, held in Athens, December 12, Dr. Ralph M. Goss was elected president; Dr. Allen C. Holliday, vice president, and Dr. James C. Holliday, secretary-treasurer, all of Athens.

ILLINOIS

New Officers.—St. Clair County Medical Association at its annual meeting held in East St. Louis, January 8, elected Dr. Henry A. Cables, East St. Louis, president; Dr. Lee D. Applewhite, East St. Louis, vice president; Dr. Charles W. Lillie, East St. Louis, secretary (reelected), and Dr. Adolph E. Hansing, Belleville, treasurer. The association authorized the formation of a branch in Belleville.

Hospital Staff Election.—At the annual meeting of the staff of Passavant Hospital, Jacksonville, January 5, Dr. Henry C. Woltman, Jacksonville, was elected president; Dr. Tully O. Hardesty, Jacksonville, secretary; Drs. Walter L. Frank, Jacksonville, and David W. Reid, Jacksonville, members of the medical board, and Dr. Charles E. Cole, Jacksonville, dean of the training school for nurses.

Chicago

Antisputting Drive.—The city ordinance against spitting on sidewalks took on new life last week on account of the prevalence of influenza. Nearly 500 people were arrested for violation of the ordinance, January 22, alone.

Laboratory Workers Form Union.—There has been formed recently in Chicago a Scientific Laboratory Workers' Union, No. 16,986, American Federation of Labor. This includes fifteen members, physicians, chemists, and bacteriologists of the Bureau of Laboratories of the Chicago Department of Health.

Personal.—Dr. John A. McGill has been elected president, and Dr. William F. Dickson, second vice president of the Illinois St. Andrews Society.—Dr. Margaret R. Otis was struck by a street car, January 20, and seriously injured.—Dr. H. Gideon Wells spoke before the Geographical Society of Chicago, January 23, on "Roumania in War and Peace."

Arrested for Morphin Selling.—John Brady, said to be known to morphin addicts as the "dope king," was arrested, January 24, charged with violation of the Harrison law. According to the policeman, Brady had at that time fifty packages of morphin which he was peddling at \$5.00 each.—The office of Dr. Edmond D. Converse was raided, January 22, and the doctor is said to have been charged with illegally prescribing morphin for drug addicts.

Internists Elect Officers.—At the fifth annual meeting of the Chicago Society of Internal Medicine, held January 26, Dr. Peter Bassoe was elected president and Dr. Clifford H. Grulee, vice president, and Dr. Charles A. Elliott was reelected secretary-treasurer. Dr. Hugh McGuigan discussed "Some Points of Interest in the Action of Chlorine-Containing Anesthetics and Hypnotics;" Dr. Frank Smithies described "Late Cardio-Respiratory Manifestations of Gassing in Returned Soldiers," and Dr. Anton J. Carlson spoke of "The Effects of Mass Starvation as Observed in Central and Eastern Europe, and the Practical Problem Involved in the Victualing of These People."

Influenza and Pneumonia.—The new cases of influenza are now beginning to decrease. During the twenty-four hours ended at 5 p. m., January 26, there were 166 deaths from influenza and pneumonia, and new cases of influenza numbered 616, and the new cases of pneumonia, 367. For three days of last week, there were more than 2,000 new influenza cases a day.—After a conference with the superintendent of the State Bureau of Registration the health commissioner announces that hospitals will be permitted to accept women with grammar school education for nursing courses, and furthermore that the bureau will cooperate in the establishment of a two years' training course for nurses.—In the seventy hospitals of Chicago there are at present

said to be 831 cases of pneumonia and influenza.—There are 1,454 empty beds in hospitals; this being due mostly to shortage of nurses which has prevented many institutions from working to capacity.

KANSAS

Public Health Laboratory Reopened.—The secretary of the state board of health announces the reopening of the Public Health Laboratory at the School of Medicine, Rosedale, under the direction of Dr. Donald R. Black, Kansas City. At this laboratory free examinations will be made of smears, and the gonococcus infection, and the Wassermann test given.

New Officers.—At the annual meeting of the Central Kansas Medical Society, held in Russell, December 17, Dr. Frederick S. Hawes, Russell, was reelected president, and Dr. Leo V. Turgeon, Wilson, secretary-treasurer. Wilson was elected as the next place of meeting.—Douglas County Medical Society at its annual meeting in Lawrence, January 2, elected Dr. Carl Phillips, Lawrence, president, and reelected Dr. Charles E. Orelup, Lawrence, vice president; Dr. Joshua R. Bechtel, Lawrence, secretary, and Dr. Elijah M. Owen, Lawrence, treasurer.—At the December meeting of the Bourbon Medical Society held in Fort Scott, Dr. Robert Aikman, Fort Scott, was elected president; Dr. Claud F. Young, Fort Scott, vice president; Dr. John C. Lardner, secretary, and Dr. Millard F. Jarrett, Fort Scott, treasurer.

MARYLAND

Personal.—Dr. H. Warren Buckler, Baltimore, has been placed in charge of the division of medical inspection of schools of Baltimore.—Dr. Edwin W. Schultz, Johns Hopkins Medical School, has gone to Leland Stanford Junior University to give a course of instruction in experimental pathology.

New Officers.—At the annual meeting of the Allegany-Garrett County Medical Society at Cumberland, January 12, Dr. George O. Sharrett was elected president; Dr. J. Kile Cowherd, vice president; Dr. Herbert V. V. Deming, secretary, and Dr. F. Garnett Cowherd, treasurer, all of Cumberland.

Influenza Increasing in Baltimore.—According to reports from the health department, influenza is on the increase in Baltimore, there having been eighty-seven new cases reported in the last twenty-four hours (January 24), while there were but thirty-three reported for the previous twenty-four hours. However, the disease is not epidemic in Baltimore and the health department does not see any reason to fear a recurrence of the havoc of 1918.

Smallpox Invasion Feared.—Owing to reports that smallpox is spreading through the lower part of Delaware, Dr. John S. Fulton, Baltimore, secretary of the state board of health, is taking precautions against allowing the disease to get over the boundaries into adjoining counties on the eastern shore of Maryland. These counties are subject to infectious invasion unless the Delaware authorities take a strong stand in the matter of intertravel in cooperation with the Maryland authorities. Dr. Fulton is considering a plan of revaccinating all persons who visit Delaware and return to the state.

Memorial Ward Opened.—The Hospital for the Women of Maryland, January 25, opened the Davis-Whitridge Memorial, a new section in the medical and surgical department, which will be used for women in moderate circumstances. The ward has been installed by the hospital to memorialize the work of Mrs. Andrew H. Whitridge, who has been connected with the hospital for ten years and was vice president of the board and Mrs. Francis A. Davis, who for fourteen years had been treasurer. The ward will contain eight semiprivate rooms and will be located on the third floor of one wing. Nurses' quarters and a chart room are attached to the ward.

United States Army General Hospital No. 2 to Go.—The rapid evacuation of Fort McHenry, both by the transfer of patients to other army hospitals and by their recovery, points to an early closing of the fort as an army hospital. There are 158 patients awaiting the arrival of a government hospital train to take them to General Hospital No. 31 at Carlisle, Pa. Col. Henry Page, commanding officer at the fort, has received orders for his transfer to the command of General Hospital No. 21 at Denver, the transfer to occur February 15. Colonel Page's successor in the command of the fort has not been named. Since December 1, about 1,040 men have been discharged from the hospital.

MISSOURI

Antivaccination League Organized.—An antivaccination league was organized at St. Joseph, January 16, by 100 persons, mostly women. The meeting voted that, despite the order of the health board that all schoolchildren must be vaccinated or must stay out of school thirty days, they would send their children to school and refuse to allow them to be vaccinated under any circumstances.

Venereal Disease Clinic.—A venereal disease clinic was opened at St. Joseph on January 17, in Community Hall, starting with forty-six patients. Several months ago, an effort was made to have the clinic financed by the city and operated by the city board of health, but the city could not find the necessary money. The local Red Cross chapter then gave \$5,000, which insures an equal amount from the Chamberlain-Kahn fund. The clinic is under the management of a committee of seven—three of the Red Cross, the three members of the city board of health and one member of the Buchanan County Medical Society.

St. Louis

New Head of Hospital Staff.—Dr. Hanau W. Loeb has been appointed chief of staff of the Jewish Hospital staff succeeding Dr. Herman Tuholske, resigned. This new position will not interfere with the work of Dr. Loeb as dean of the University of St. Louis Medical College.

Kentucky Visitors.—At the meeting of the St. Louis Medical Society, January 27, Dr. Louis Frank, Louisville, read a paper on "Blood Studies in Connection with Surgery" and Dr. Granville S. Hanes, Louisville, one on "Local Pain and Other Symptoms Associated with the Infection of the Anal Tissue." Prior to the meeting, Drs. Frank and Hanes were guests of honor at a dinner at the University Club.

NEW MEXICO

Communicable Disease.—The health department reports at least 100 cases of smallpox of mild character in Tularosa.—An outbreak of scarlet fever is reported at Ojo Caliente.

Venereal Clinic Opened.—January 5, a free clinic for venereal disease was opened at Santa Fe under the auspices of the state board of health. Similar clinics are to be opened at Deming and Albuquerque.

State Laboratory Opened.—The state laboratory, which is being provided jointly by the state board of health and the University of New Mexico at Albuquerque, was opened, January 15, in charge of a trained technician.

New Officers.—At the annual meeting of the Bernalillo County Medical Society, held in Albuquerque, December 3, the following officers were elected: president, Dr. Cowan C. Meachem, Bernalillo; vice presidents, Drs. John R. Van Atta, Albuquerque, Arno Klein, Albuquerque; secretary-treasurer, Dr. Frank E. Tull, Albuquerque, and corresponding secretary, Dr. George S. McLandress, Albuquerque.

NEW YORK

New York City

Influenza on Liner.—The Spanish liner *P. de Sastre* from Barcelona, which reached Quarantine, January 17, had aboard thirty-one patients with influenza among 414 steerage passengers. The patients were all removed to Swinburne Island, and the vessel was fumigated.

New Tuberculosis Association Organized.—The antituberculosis work in New York City has been taken over by a new organization, the New York Tuberculosis Association, Inc., with Dr. James Alexander Miller, president; Mr. Homer Folks, vice president, and Dr. John S. Billings, Jr., director.

New Regulations in Regard to Quarantine Periods.—At a recent meeting of the department of health, the following regulations governing the isolation of persons affected with an infectious disease and amending Section 89 of the Sanitary Code were adopted:

For the purpose of these regulations, the minimum period of quarantine shall be as follows:

- Diphtheria: Twelve days from onset.
- Scarlet Fever: Thirty days after the onset of the first symptoms.
- Cerebrospinal meningitis: Fourteen days from the onset.
- Acute anterior poliomyelitis: Three weeks from the date of onset.
- Typhoid Fever: Until ten days after the patient's temperature reaches normal.

Wood Alcohol Poisoning Reportable.—At a meeting of the board of health, held, December 31, the following amendment

to the Sanitary Code, making wood alcohol poisoning reportable to the health department, were adopted:

It shall be the duty of the manager or managers, superintendent, or person in charge of every hospital, institution, or dispensary in the city of New York to report immediately to the Department of Health the name, age, and address of every occupant or inmate thereof, or person treated therein, affected with wood alcohol or wood naphtha poisoning; and it shall also be the duty of every physician in said city to make immediately a similar report to the Department of Health relative to any person found by such physician to be affected with wood alcohol or wood naphtha poisoning.

Influenza Becomes Epidemic.—The tabulations of the health department, January 23, show that during the preceding twenty-four hours 1,332 new cases of influenza were recorded, and 406 new cases of pneumonia for the same period. Since January 1, when the outbreak officially is reckoned to have begun, there has been a total of 3,096 cases of influenza and 3,336 cases of pneumonia. Comparison with the figures of Oct. 4, 1918, which is taken by the department of health as the day of that epidemic corresponding to January 23 of the present outbreak, shows that while about the same number of new cases were reported on these dates, the number of deaths reported was about twice as large as on the former date. A conference of the directors of the health department bureaus and the sanitary superintendents of the various boroughs was held and all department administrative details of the attack on the epidemic were arranged. The main headquarters of the department of health will remain open twenty-four hours of the day and seven days a week until the epidemic has passed. The board of estimate, on the request of Health Commissioner Copeland, has appropriated \$80,000 of special revenue bonds to the health department as an emergency fund with which to fight the epidemic. The department of health is not recommending the use of vaccines in combatting the epidemic.

OHIO

Service Physicians Banqueted.—The eleven physicians of Knox County who served during the world war were guests of honor at a banquet given by the Knox County Medical Society, January 13, at Mt. Vernon.

New Interest in Health Matters.—Public health affairs at Canton have taken on new life. Sentiment has been created in favor of adequate health protection so that \$29,630 has been allowed by the city council as a budget for the first six months of the year, or \$17,630 more than the last budget allowed. Applications are being received for chief medical officer, two physicians as full-time health officers, one chief nurse, four public health nurses, four food and meat inspectors, one chief of laboratory, one assistant veterinarian and one assistant clerk in the health office.

Personal.—Dr. James H. Lowe, for twelve years health officer of Piqua, has been reelected for a term of two years.—Dr. Guy T. Goodman, Mansfield, for nine years a member of the board of health and city health officer has resigned.—Dr. Ulysses G. Murrell, Wilmington, has been appointed registrar of the state bureau of vital statistics succeeding Dr. John E. Monger, Greenville, resigned.—Dr. Delbert J. Miller, Alliance, sustained a fracture of the jaw, and a number of cuts and bruises of the face and head when his automobile was struck by a train at a grade crossing.

Supervision of Hospitals.—The State Department of Health of Ohio has organized a bureau of hospitals and the bureau is now working out plans for carrying out the provisions of the new law enacted by the state legislature with reference to the supervision of hospitals. The latter are required to make reports to the state, and forms for the report have been prepared. Annual reports covering work done during 1919 will be filed, March 15. Under a resolution adopted by the legislature, the department is also undertaking a general survey of the hospital and dispensary facilities of the state, and these institutions are being registered as the first step in the study.

Organization Under New Health Law.—Columbiana, Warren, Morrow, Geauga, Pike, Auglaize, and Belmont counties are the first in the state to place their new general district health organization in operation. Columbiana county reports a budget of \$10,000; Morrow, of \$6,750; Warren, of \$4,600; Pike, of \$5,500, and Geauga, of \$5,000, Columbiana, Morrow and Pike counties will receive the maximum state subsidy of \$2,000 while the state aid for Warren County will amount to \$1,600 and of Geauga County to \$1,700. Columbiana and Morrow have appropriated \$3,000 each for a health commissioner's salary and will probably be able to obtain

whole-time officers. The other counties have made appropriations which will provide for parttime commissioners.

Protection Against Water-Borne Diseases.—Ohio is said to share with Massachusetts the place at the top of the list of states with sanitary control of public water supplies, with a score of 97 per cent. This protection has been effected by laws providing for state inspection and approval of all water supply projects and for state examination and supervision of supplies in use, allowing for all sources of possible danger. The state department of health shows that all but fifty of the 300 public water supplies of the state are of unquestionable purity; that only about 10 per cent. of the four million people served by public water supplies use water from doubtful or unsafe sources, and that only ten communities, with a population of 100,000, use water definitely classed as unsafe.

PENNSYLVANIA

Mont Alto to Be Enlarged.—The state has purchased several hundred acres of land contiguous to the department of health sanatorium at Mont Alto, and now controls virtually all the properties abutting the institution.

Board Has No Authority to Revoke Licenses.—Under a ruling made by Deputy Attorney General Swoope, January 9, the board of medical education and licensure has no authority to revoke the license of a medical practitioner who has been convicted of an offense while in practice, sentenced to the penitentiary and released on bail pending an appeal. It has no power to revoke either in the case of one convicted of repeated offenses or of one who has escaped conviction through legal technicalities until the appellate courts have passed on the appeal.

New Officers.—Allegheny County Medical Society at its annual meeting in Pittsburgh, January 13, elected Dr. John J. Buchanan, Pittsburgh, president; Drs. George C. Johnston, Pittsburgh, Thomas A. Miller, Bellevue, Robert W. Allison, Wilkingsburg, Gustav F. Berg, Pittsburgh, and Glenn M. Pierce, McKeesport, vice presidents; Dr. William H. Mayer, Knoxville, secretary, and Dr. Elmer E. Wible, Pittsburgh, treasurer.—Erie County Medical Society at its annual meeting, January 6, elected the following officers: Dr. Katharine H. L. Wright, Erie, president; Dr. John A. Darrow, Erie, Dr. Charles C. Kemble, Erie, vice presidents; Dr. James T. Strimble, Erie, secretary, and Dr. James E. Croop, Erie, treasurer.—Dauphin County Medical Society at its annual meeting in Harrisburg, January 6, elected the following officers: president, Dr. Hewitt C. Myers, Steelton; vice presidents, Drs. Richard F. L. Ridgway and John W. MacMullen, Harrisburg, and secretary, Dr. Charles M. Rickert, Millersburg.

Philadelphia

Personal.—Mayor Elect Moore has announced that Dr. Norman H. Taylor will be appointed as assistant director of health under Dr. C. Lincoln Furbush.

Influenza at Navy Yard.—One hundred cases of influenza developed at the League Island Navy Yard between January 21 and 23. There are no malignant symptoms, but every care is being taken to prevent its spreading. Social centers and meeting places at the navy yard have been closed.

Women's College Drive.—The campaign of the Women's Medical College, Pennsylvania, to raise \$250,000 was opened, January 8. It is intended that part of this fund, if raised, will finance a department of preventive medicine. Sixteen thousand one hundred and eighty-seven dollars were pledged on the first day of the drive.

Third Smallpox Outbreak.—Following the discovery of two cases of smallpox in the northwestern section of the city, 1,500 persons within the boundaries of Thirty-First and Huntingdon and Thirty-Second and York streets were vaccinated, January 22. These cases were also traceable to the Georgetown, Del., area for both the man and his wife had paid a visit to Dagesboro, fourteen miles south of Georgetown. Up to January 23, 4,447 persons had been vaccinated following the three outbreaks.

City Prepared to Fight Influenza.—Should the emergency arise and influenza return to this city in epidemic form, the health department is preparing to meet it. The director asks that all cases be reported to the health bureau and laboratory tests are being made of all cases so far reported, that the exact nature of the malady may be determined. Four hundred beds at the Philadelphia General Hospital have been prepared and provisions made for an extra corps of physicians and nurses. The president of the traction

company has been requested to forbid overcrowding of cars and to insure proper ventilation. A bulletin has been issued by Dr. Walter S. Cornell, chief medical inspector of schools, that will reach every child in the public schools.

TENNESSEE

Negro Hospital for Bristol.—Funds are being raised to erect a \$25,000 hospital for colored people at Bristol. It is proposed that the hospital be in charge of local colored physicians and that it be conducted on a cooperative basis.

Personal.—Dr. Robinson Bosworth, St. Paul, Minn., has given his services to Memphis for a few months, working in cooperation with the city health department in a campaign against tuberculosis.—Dr. Rufus P. Sullivan, Cleveland, has been elected physician of Bradley County.—Dr. James B. Cox, Huntington, has been reelected health officer of Carroll County.—Dr. John R. Thompson, Nashville, has been reelected health officer of Davidson County.

Society Meetings.—At the eighth annual meeting of the Tennessee Academy of Science at Nashville, November 28, the following officers were elected: Dr. William F. Glenn of Vanderbilt University, Nashville, president, and Prof. C. F. Gordon of the University of Tennessee, Knoxville, editor.—At the joint meeting of the Nashville Academy of Medicine and Davidson County Medical Society, January 6, Dr. William C. Dixon was elected president; Dr. Samuel M. Bloomstein, vice president, and Dr. John Witherspoon, secretary (reelected).—Childs County Medical Society at its annual meeting in Pulaski, January 2, elected Dr. George D. Butler, Pulaski, president; Dr. William H. Cole, Minor Hill, vice president; Dr. Charles A. Abernathy, Pulaski, secretary, and Dr. George C. Grimes, Pulaski, treasurer.—At the annual meeting of the Mountain City Academy of Medicine and Surgery (colored), Chattanooga, the following officers were elected: president, Dr. Clarence F. Bass; vice president, Dr. Lewellen L. Patton; secretary, W. B. Davis, and treasurer, R. W. Allen.

TEXAS

Venereal Disease Clinic Discontinued.—The venereal disease clinics at Dallas and Galveston were closed, January 1, on account of lack of funds.

Personal.—Dr. Azariah W. Parsons, formerly chief surgeon of the Mexico national railroad in the city of Mexico, has located at Corpus Christi.—Dr. William E. Huddleston, who has been taking graduate work in England has returned to Galveston.—Dr. Ethel M. Lyon Heard, Austin, has been appointed physician for women at the state university, Austin.

Hospital Items.—The City Hospital at Yoakum is being erected under the supervision of L. Harrington Company, architects. The cost will be \$60,000.—Construction work is in progress on a new hospital at Taylor which is being built by Drs. Edmund Doak, Eric W. Stromberg and Thomas D. Vaughan, Taylor, and Dr. John H. Vaughan, Liberty Hill.

New Officers.—The Fourth District Medical Society at its annual meeting in Coleman, December 2 and 3, elected Dr. Samuel N. Aston, Coleman, president, and Dr. John M. Nichols, Bangs, secretary-treasurer. Ballinger was selected as the place of meeting for 1920.—North Texas District Medical Association met in Fort Worth, December 9 and 10, and elected Dr. Martin L. Wilbanks, Greenville, president; Dr. Marquis E. Gilmore, Fort Worth, vice president; Dr. David L. Bettison, Dallas, secretary (reelected), and Dr. Sidney J. Wilson, Fort Worth, treasurer. Waxahachie was selected as the next place of meeting.—Physicians of Eastland organized a medical society, January 9, to be known as the Medical Society of the City of Eastland, electing Dr. Herbert B. Tanner, president, and Dr. Edward C. Ferguson, secretary-treasurer.—Dallas County Medical Society at its annual meeting held, December 11, elected Dr. William T. Baker, Dallas, president; Dr. Henry B. Decherd, Dallas, vice president, and Dr. William W. Fowler, secretary-treasurer.

CANADA

Fight Venereal Diseases.—Preliminary organization has been completed for carrying out the campaign against the venereal diseases by the federal provincial boards of health of Canada. Dr. Charles A. Hodgetts, Ottawa, has been appointed chairman of the Ontario organization, and Dr. Robert R. McClenahan, Hamilton, secretary. Drs. John G. Fitzgerald, Toronto; Frederick Etherington, Kingston; Douglas G. Storms, Hamilton; Frederick W. Luney, London, are on the committee.

Guards Up Against Influenza.—The federal department of health reports that there is no information available that influenza is anywhere epidemic in Canada. All the provincial boards of health are on the watch for the disease. Especially is Ontario taking strict precautions against an invasion, and has already opened a register for physicians and nurses who will be prepared to join in any campaign toward controlling the malady.

Hospital News.—The General Hospital and the Western Hospital, Montreal, are going to amalgamate. It is hoped to make the combined hospitals the greatest institution in Canada, and a hospital act is being brought into the Quebec legislature to ensure the success of the scheme. It has been found no longer possible to finance the institutions separately and by the new arrangement financial aid is looked for from the province.—Toronto is going to have a new Reception Hospital. The site has been definitely decided on and is to be the old grounds of Trinity University. Efforts were made to have this hospital located near the General Hospital but without success. It has to be built by the city, but the administration is under control of the province.

GENERAL

Medical Officers for Poland Obtained.—Gen. Robert E. Noble has requested us to announce that the fifty medical officers required for duty for the Red Cross in Poland have been obtained, and that no further applications will be considered.

Addition to Hospital Site.—Senator Spencer of Missouri has introduced a joint resolution permitting the expenditure of \$350,000 for the purchase of 26 acres of land contiguous to the Walter Reed General Hospital, Takoma Park, Washington, D. C.

Anesthesia Research Organization.—The National Anesthesia Research Society has been organized with the avowed purpose of collecting data and of prosecuting original research in the science of anesthesia. The research committee is headed by Dr. F. Hoeffler McMechan, Avon Lake, Ohio.

Sickness Insurance Discussed.—At the twentieth annual meeting of the National Civic Federation held in New York City, January 29 and 30, among the topics for discussion were "Compulsory Sickness Insurance and a Substitute for It." Frederick L. Hoffmann, a member of the committee of foreign inquiry, who has just returned from five months' study of the operation of the British National Health Insurance act, reported his findings.

Bill for Construction of Hospitals for Soldiers.—Senator France of Maryland introduced, January 24, a bill endorsed by the Public Health Service for the appropriation of \$78,000,000 for the construction of hospitals for soldiers who are beneficiaries of war risk insurance. In connection with this legislation Senator France said:

It is imperative that we should have legislation providing hospital facilities for diseased and disabled soldiers in the world war. Up until this time provision made for the treatment of these soldiers has been most inadequate, and many men who should be receiving treatment in hospitals are deprived of proper care because of neglect to provide hospital facilities.

It is estimated that at the present time the government is in need of hospital accommodations in the amount of 7,200 beds for general medical and surgical cases, of 12,400 beds for tuberculous cases and 11,000 beds for nervous and mental cases. The actual facilities of the Public Health Service at the present time are not in excess of 7,200 beds. Members of the American Legion have been making earnest protests because of the failure of the government to provide for proper care of our soldiers in hospitals. Throughout the West in many cities, tuberculous soldiers and those suffering from nervous and mental diseases are unable to secure any accommodation in government hospitals. An identical bill will be introduced in the House of Representatives.

Tariff on Scientific Instruments and Apparatus.—The subcommittee of the Senate Committee on Finance has completed its hearings and will meet, February 2, for final action on a bill placing a tariff on surgical and dental instruments and scientific and laboratory apparatus. The House of Representatives passed the bill fixing the tariff on these articles at 45 and 60 per cent., respectively. No opposition was made to this bill and it is likely that the committee will approve the house bill, which is designed to encourage the manufacture of these articles in the United States and avoid the danger of foreign competition. Representing the government

were Dr. W. F. Hildebrand of the bureau of standards; Lieut.-Col. M. A. Reasoner of the field medical supply depot, and Col. F. F. Russell, Army Medical School, and representing chemical and scientific societies were Mr. H. C. Parmalee and Dr. Charles H. Herty.

Bequests and Donations.—The following bequests and donations have recently been announced:

Pennsylvania Hospital, Philadelphia, \$1,000 and the residue of his estate in equal shares to the Jewish Maternity Hospital, Philadelphia; Jewish Seaside Home, Atlantic City, and National Farm School, Doylestown, by the will of Dr. John Moss, Jr.

Methodist Hospital, Philadelphia, \$1,000 by the will of Louise M. Pepper.

St. Vincent's Orphan Asylum, Tacony, Pa., \$1,000 by the will of Herman Buchborn.

Methodist Episcopal Church of northwestern Iowa as a site for a two-hundred bed hospital, a 280 acre tract at Sioux City, valued at \$100,000, donated by Dr. William Jepson.

Campaign Fund of the Woman's Medical College of Pennsylvania, for the endowment of a scholarship in memory of his mother, Elizabeth Agnes Moore Deaver, a donation of \$5,000 by Dr. Harry C. Deaver, Philadelphia.

Wichita Falls, Texas, for the endowment fund of a new hospital, a donation of \$50,000 by J. A. Kemp.

Medical Department of the University of Pennsylvania, Philadelphia, for the establishment of a chair of gynecology, a bequest of \$50,000 by the estate of Dr. William C. Goodell.

Senate Appropriates Half Million Dollars to Combat Influenza.—The Senate has passed a joint resolution appropriating \$500,000 to be used by the Public Health Service in combating influenza. The resolution directs the Public Health Service to investigate influenza and allied diseases in order to discover their causes and prevent their spread. It requires the allotment of money to universities, colleges and other research institutions for scientific investigation. The Public Health Service is accorded the privilege of making selection of such institutions. A forceful debate occurred in the Senate prior to the adoption of the resolution, Senator King of Utah opposing the resolution and objecting to the "constant encroachments of the Public Health Service organization." He said: "We will soon have the United States furnishing doctors, nurses and hospitals for all the people, with the result of hundreds of millions of dollars being taken annually from the people." The resolution originally provided for an expenditure of \$1,000,000. Senator France in charge of the resolution acquiesced in the amendment, reducing the amount to \$500,000. The resolution now goes to the House of Representatives.

League of Red Cross Societies.—The International Red Cross Committee has issued a call for the first convention of the general council of the League of Red Cross Societies, to be held in Geneva, March 2. The league was founded in Paris, May 5, 1919, by the national societies of the United States, Great Britain, France, Italy and Japan, with which the societies of many other countries have since joined. Control is vested in a general council composed of representatives of all member societies, but in the intervals between the regular meetings this control is exercised by a governing board of fifteen members, of which Henry P. Davison, American Red Cross, has been elected chairman. At a preliminary conference in Cannes, April, 1919, the establishment of a bureau of health with a director, advisory council and permanent staff was recommended. The tentative program includes an intensive campaign against typhus fever, the extension and development of child welfare work, and the encouragement of worldwide adoption of definite programs for establishment of public health laboratories, for compulsory registration of vital statistics, and for the control of tuberculosis, venereal diseases and malaria. The permanent headquarters of the league are at 9 Cour de St. Pierre, Geneva, Switzerland.

Cumming, Surgeon-General, U. S. Public Health Service.—As we go to press the newspapers announce that the President has nominated Dr. Hugh S. Cumming as Surgeon-General of the U. S. Public Health Service to succeed Surgeon-General Rupert Blue, whose second term expired January 13. Born at Hampton, Va., August 17, 1869, Dr. Cumming was graduated M.D. from the University of Virginia in 1893, and from the University College of Medicine, Richmond, in 1894. He was commissioned assistant surgeon May 25, 1894, passed assistant surgeon five years later, attained the rank of surgeon March 15, 1911, of senior surgeon Nov. 8, 1918, and was appointed assistant surgeon-general March 6, 1919. Dr. Cumming's professional interest has been mainly in the field of preventive medicine and quarantine. Prior to the war, he was for some years stationed at the Hygienic Laboratory in Washington, before which time he had seen many years of service as chief quar-

antine officer at San Francisco and other ports. He is a frequent contributor to the literature of sanitary science and has made intensive studies of pollution of watersheds with special reference to the shellfish bearing areas, the results of which are embodied in public health bulletins issued by the government. At present he is on duty at Constantinople in connection with a concerted campaign for the control of typhus fever. During the war Dr. Cumming was detailed for special duty with the Navy Department.

Midwinter Conference on Public Health and Legislation.—The annual Midwinter Conference on Public Health and Legislation will be held Thursday, March 4, 1920, in the South Parlor, Auditorium Hotel, Michigan Avenue and Congress Street, Chicago. The program will be as follows: Morning.—

1. Call to Order, 9:30 a. m.
 2. Chairman's Address, Dr. Victor C. Vaughan, Ann Arbor, Mich., chairman, Council on Health and Public Instruction, American Medical Association.
 3. Secretary's Report, Dr. Frederick R. Green, secretary, Council on Health and Public Instruction, American Medical Association.
 4. "Standardization of Public Health Activities," Dr. George E. Vincent, president, Rockefeller Foundation.
 5. "Standardization of State Public Health Organizations," Dr. Charles V. Chapin, commissioner of health, Providence, R. I.
 6. "Standardization of Municipal Health Organization," Dr. Allen McLaughlin, Assistant Surgeon-General, U. S. Public Health Service.
 7. General Discussion, opened by Dr. C. St. Clair Drake, commissioner of health, Springfield, Ill., and Dr. Ennion Williams, commissioner of health, Richmond, Va.
- Afternoon, 2 p. m.—Symposium on "Health Education of the Public."
1. "Health Education in the Public Schools—Thirty Years' Experience in Michigan," Dr. Victor C. Vaughan, Ann Arbor, Mich.
 2. "Health Education and Activities in College and Universities," Dr. John Sundwall, director, Students' Health Service, University of Minnesota, Minneapolis.
 3. "Health Education a Function of Municipal Health Department," Dr. Haven Emerson, New York.
 4. "Health Education a Function of State Health Department," Dr. W. S. Rankin, secretary, state board of health, Raleigh, N. C.
 5. "Health Education a Function of the Federal Government," Dr. Charles V. Bolduan, director, Division of Public Health Education, U. S. Public Health Service.
 6. Discussion opened by Dr. John M. Dodson, Chicago; Prof. W. B. Owen, superintendent, Chicago Normal College.

FOREIGN

American Hospital in Poland.—A new hospital has been opened at Vilna, Northwest Poland, by the American Red Cross.

Congress for History of Medicine.—The Société française d'histoire de la médecine has organized an independent congress for the history of medicine and pharmacy, to be held at Antwerp, Aug. 7 to 12, 1920, at the same time as the Kermesse and the festival of the seventh Olympiad. Among the principal subjects appointed for discussion are medical iconography and epigraphy; medical bibliography, and a chapter from the history of public charities (hospitals, etc.) in every country.

Personal.—Dr. Paul Sabatier, Toulouse, and Pierre Paul Emile Roux, Paris, have been elected honorary members of the British Royal Association.—Dr. Hanz Gertz of the Physiological Laboratory of Karolinska Institut, Stockholm, has been awarded the Jubilee Prize by the Swedish Medical Association for his work on the functions of the labyrinth.—Dr. Harold Pringle, lecturer on histology and assistant in physiology in the University of Edinburgh, has been appointed professor of physiology in Trinity College, Dublin, succeeding the late Sir Henry Thompson.

Memorial for the Interns of Paris Hospitals.—In memory of the interns and former interns of the hospitals of Paris who gave their lives for their country, a memorial service was held in turn recently in the Roman, the Protestant and the Jewish places of worship. A monument is to be erected to perpetuate their memory. It will stand near the entrance of the Hotel-Dieu, and bear the names of all the interns and ex-interns who died for France. Subscriptions for the monument are to be sent to M. Arnette, 2, rue Casimir-Delavigne. The Société médicale des hôpitaux started the subscription list with 1,000 francs.

Interallied Graduate Course on Tuberculosis at Paris.—This course of lectures on various phases of the organized fight against tuberculosis has been organized by the Ecole interalliée des hautes études sociales, 10, rue de la Sorbonne. The lectures are held Tuesday afternoons at 5:30. Calmette will speak on tuberculosis in the invaded regions; Rist, on the partisans of compulsory declaration; a member of the lower house, on legislation on tuberculosis; Mlle. Chaptal, on private works, and others on the stand of labor in regard

to declaration, on the work of the Red Cross, the climatic resorts of France, etc.

Semicentennial of the "Correspondenz-Blatt."—With 1920 the important Swiss weekly, the *Correspondenz-Blatt für schweizer Aerzte*, enters on its fiftieth year. Instead of the previous book page, 7 by 9½ inches, it appears in a new form, the pages about 10 by 13 inches. This change is made, it is stated, principally on account of the advertisers. The name of the weekly is also changed to the *Schweizerische medizinische Wochenschrift*, but the editors, publishers, and the principles of the journal remain the same. It always publishes the reports of the various medical societies in both German and French Switzerland, and the original articles are published indiscriminately in German or French. In its new dress it falls into line with the weeklies of Germany and Austria.

Death of Severin Jolin.—The death of the newly appointed president of the Swedish Medical Association is reported, Prof. Severin Jolin, incumbent of the chair of chemistry and pharmacology at Stockholm and since 1917 at Upsala. He has published numerous works on chemistry and pharmacology and on the newer remedies, and was the representative of Sweden at many international scientific gatherings. To him is ascribed in large part the high standard of the Swedish Pharmacopoeia as he has taken an active share in the revision of the different editions. Several years of research on the thyroid, especially on its iodine content, led him to the conclusion, in 1906, that iodine is not an indispensable element in the thyroid, but is merely stored there when there happens to be an excess of iodine in the body.

Deaths in the Profession.—In Italy, Dr. Antonio Riga, aged 87, of Riga's disease fame. He described it in 1881 as pseudomembranous sublingual frenulitis. Riga's disease is now defined in the dictionaries as cachectic aphthae.—Dr. H. Gerber, professor of laryngology at the University of Königsberg.—Dr. V. Mucha, formerly director of the Vienna general hospital, aged 76.—Dr. O. Tunmann, professor of pharmacognosy at the University of Vienna.—Dr. B. Baginsky, privat-docent of ear, nose and throat diseases at the University of Berlin.—Sir Thomas Richard Fraser, M.D., Edinburgh, 1862; F.R.C.P., Edinburgh, 1869; formerly president of the Royal College of Physicians, the Medico-Chirurgical Society, the Royal Medical Society, Edinburgh, and the Association of Physicians of Great Britain and Ireland; president of the England Plague Commission from 1898 to 1900; died at his home in Edinburgh, January 5.

The International Health Resort Congress at Monaco.—Great preparations are being made for the Congress for the Expansion of Climatic, Mineral Springs and Baths, and Sea-Bathing Health Resorts which is to be held at Monaco in April. All the Allied and friendly nations have been invited to participate, and preparations have been under way for this congress since early in 1916. It aims to acquaint the world with what these countries have to offer in the way of health resorts, and an exposition in connection will open April 20 and continue into 1921. The exposition will comprise a section for historical objects of interest in this line, a scientific and therapeutic exposition of the various spas, etc., a section of views and data for tourists, a moving picture section, and an industrial and commercial exhibit. There are in fact to be six separate congresses: (1) hydrology and geology; (2) hygiene and climatology; (3) thalassotherapy; (4) spas, seaside and mountain health resorts; (5) mountain climbing (alpinism); (6) touring.

Honors for American Women Physicians in France.—The *Journal officiel* for Dec. 22, 1919, gives a list of seven American medical women honored by the French government with the Gratitude of France medal. Four are said to have served with the utmost devotion at the Hôpital des dames américaines at Luzancy "where the populace had not had any surgical care during the preceding four years of the war": Dr. Charlotte Fairbanks (from St. Johnsbury, Vt.) "performed more than 500 operations and tended the people with extreme devotion;" Dr. Inez A. Bentley (from Kings Park, N. Y.) "by her incessant efforts maintained the equipment of the medical and surgical wards and served as sub-director of the hospital;" Dr. Mary L. Evans (from Middletown, Conn.) "rendered most devoted services to the people" as bacteriologist, director of the laboratory and pharmacy of the hospital, as also Dr. Mary MacLachlan (from Middletown, Conn.) director of the hospital and dispensary. The official list includes further Dr. Mary E. Lapham (from Highlands, N. C.) of the American Red Cross "for her untiring efforts in organizing and conducting a clinic at

la Rochelle;" and Dr. Jay Manwaring (from Norwich, Conn.) "for the medical services rendered by her for two years to the people of thirty villages in the Château-Thierry region." All the above were silver medals. A bronze medal was awarded further to Dr. Edith (Elizabeth?) Mercelis (of Montclair, N. J.) who "helped to organize and conduct a number of *œuvres* for the benefit of France." The list is reproduced in the first issue of the *Presse médicale* for 1920.

LATIN AMERICA

Influenza in Cuba.—It is reported from Havana that there are over 6,000 cases of influenza in that city.

Dr. Leiva Returns to Bogatá.—Dr. Leiva Pereira has returned to Bogatá after several years of absence. During the war he volunteered his services in French hospitals and has been decorated by the French government. He was also decorated by the American Ambulance which went to France at the beginning of the war, where Dr. Leiva demonstrated and applied an apparatus he had devised for treatment of fracture of the humerus.

Deaths in the Profession.—Our exchanges mention the death, October 22, of Dr. Pedro Maria Ibañez, one of the founders of the Academia Nacional de Medicina of Bogatá, a leader in the progress of science in Columbia, and author of numerous works, including a history of medicine in Columbia.—From Vera Cruz is reported the death of Dr. Esteban Rojo, a Cuban physician who had lived in Mexico for more than thirty years, three of whose sons are physicians.

The Recent Earthquakes in Mexico.—According to a letter just received from a Vera Cruz physician, the recent earthquakes caused untold damage and suffering in that region. The trepidation still continues and hills and mountains keep on falling down or breaking apart. San Miguel, a very high peak not far from the Orizaba volcano, broke apart some three kilometers in its center, giving origin to a new volcano which spurts enormous quantities of boiling water that destroys everything in its path. So far fifteen towns have been destroyed by this water. At Jalapa the victims exceed 10,000 and the wounded are also very numerous. Many oil wells are flowing unchecked, and measures will have to be taken to prevent a conflagration. Physicians were among the first to render assistance throughout the territory affected. The representative of the White Cross at Vera Cruz furnished all the medical supplies he had on hand to treat the emergency cases.

Death of Dr. Liceaga.—Dr. Eduardo Liceaga, one of the most prominent physicians and sanitarians of the western continent, died, January 15, at his home in Mexico City. He was for many years president of the national public health service, and had to his credit the stamping out of yellow fever, practically throughout Mexico. He also established the Pasteur Institute of Mexico City, the Maternity Home and Children's Hospital and was responsible for having brought the sanitary service of that country to a high degree of excellence before the recent disturbances began. In recognition of his many services to the cause of medicine in Mexico, he was appointed honorary president of the Mexican Medical Association on its organization, a few months ago. Dr. Liceaga was well known in this country, having attended many medical and sanitary meetings and participated actively in the various international sanitary conferences held in Washington. He was also a member of the International Sanitary Bureau of Washington since its foundation until his resignation as head of the Mexican Public Health Service. Dr. Liceaga was the author of numerous contributions on sanitary subjects, especially yellow fever.

CANAL ZONE

New Society Officers.—At the one hundred and sixtieth meeting of the Medical Association of the Isthmian Canal Zone held at Ancon, December 19, the following officers were elected: president, Dr. Wallace E. Hubbard; vice president, Dr. Cornelius D. Briscoe, and secretary-treasurer, Dr. Nathan B. Kupfer, all of Ancon.

Civil Service Examination.—The United States Civil Service Commission announces open competitive examinations for physicians in the Panama canal zone service to be held, February 18 and March 17. These positions are open to men and women, with a beginning salary of \$200 a month, increasing to \$300 or more. Applicants must be unmarried, must have had at least one year of graduate hospital experience, and must be between 22 and 31 years of age, unless entitled to preference because of military or naval service.

Government Services

Health Conditions of the Army

The weekly summary of health conditions in the army for the week ending January 16 indicates a higher admission rate and noneffective rate than previously, due to the prevalence of epidemics of mild influenza, complicated in some cases also by pneumonia. The disease was especially prevalent in Camps Grant, Custer, Dodge and Fort Sheridan. Among the American Forces in Germany fewer cases of influenza were reported than for the previous week, while pneumonia and measles showed a slight increase.

Report of Surgeon-General of the Public Health Service

Surgeon-General Blue points out that the United States Public Health Service, through new legislation, has had its work extended to include a division of venereal diseases, a reserve for the Public Health Service and certain activities under the War Risk Insurance Act. The service has outlined an "After the War" program to increase sanitation, to prevent epidemic and other diseases, and to raise the standard of physical health. The program calls for the active cooperation of federal, state and local health authorities, as well as volunteer health agencies. The Division of Scientific Research has made investigations of many diseases, sanitation and sewerage and the pollution of navigable streams and lakes. It has also studied rural sanitation, interested itself in the prevention of the spread of trachoma and, through the hygienic laboratory, controlled the sale of viruses, serums and antitoxins. Special studies have also been devoted to pellagra. Industrial physiology was studied with the assistance of Dr. Frederick S. Lee, who is in the reserve corps, and special educational courses were given by consulting hygienists, C. E. A. Winslow and E. R. Hayhurst. Throughout the report appear the names of well known hygienists and sanitarians whose services have now been made available through the passage of the reserve act. Special sections of the report are devoted to the hygienic laboratory, the domestic quarantine division, extra-cantonment zone sanitation, maritime quarantine, sanitary reports and statistics, also to public health education, marine hospitals, venereal diseases, etc.

Under the heading "Needs of the Service," it is pointed out that most important is the provision of an adequate building for the bureau in Washington. During the past two years the service has experienced the greatest expansion in its history and now occupies space in several widely separated buildings.

He also requests much increased appropriation in order to carry into effect the extensive "After the War" program to provide for additional publicity for public health education.

A pleasing feature of the report is the statement of the names of the personnel of the various divisions, giving credit to those whose united efforts have made the growth of the service and its efficiency possible.

Government to Sell Medicines and Hospital Supplies to Hospitals and Institutions

The director of sales of the War Department has announced that the Surplus Property Division, Office of the Quartermaster General of the Army, will offer for sale quantities of drugs, surgical instruments, surgical dressings, and hospital equipment. The fixed prices will be materially below present market quotations. State and municipal hospitals, free clinics and similar institutions will be entitled to purchase for a period of thirty days, beginning Jan. 29, 1920, and ending Feb. 29, 1920. The materials to be sold were bought by the War Department for use during the war and have been declared surplus because the quantities on hand are in excess of the Army's present requirements. A list of materials, showing the quantities available, location, price and other necessary information may be obtained from any Zone Supply Officer or from the Surplus Property Division, Munitions Building, Washington, D. C. The prices quoted are f.o.b. point of storage. A certified check, cash or liberty bonds, amounting to 10 per cent. of the total purchase must accompany all orders together with shipping instructions when purchase is made by other than state,

county, or municipal institutions. A ninety-day credit will be granted to purchasing agents of state, county, or municipalities when requested and no deposit is required by them. All other purchasers will be required to make payment in full before the materials are delivered.

The sale of narcotics will only be made to the classes of persons who have registered and paid a special tax as required by the Harrison narcotic law. Any hospital, institution, or purchasing agency representing charitable organizations in different cities or counties may purchase the entire quantity of any one or a number of items and may resell, issue or divide any portion with other hospitals or charitable institutions. The government, however, will not permit the resale of any of the articles at prices above those paid to the government except that handling charges may be added.

Orders may be made through the nearest of the following Zone Supply Offices: Army Supply Base, Boston, Mass.; 461 Eighth Avenue, New York; 21st Street and Oregon Avenue, Philadelphia; Coca Cola Building, Baltimore, Md.; Transportation Building, Atlanta, Ga.; Army Building, 15th and Dodge Streets, Omaha, Neb.; Fort Mason, San Francisco, Calif.; 17th and F Streets, Washington, D. C.; Newport News, Va.; Jeffersonville, Ind.; 1819 W. Thirty-Ninth Street, Chicago, Ill.; 2d and Arsenal Streets, St. Louis, Mo.; Audubon Building, New Orleans, La.; San Antonio, Texas; New Cumberland, Pa.; Columbus, Ohio; or to the Surplus Property Division, Munitions Building, Washington, D. C.

Foreign Correspondence

LONDON

Jan. 10, 1920.

Sir William Osler

The great gap in the profession made by the death of Osler is manifest in the pages of tribute in the journals by the leaders of the profession. The finest is by the man he affectionately called his "brother Regius of Cambridge"—a kindred spirit as suggested in the previous notice. Writing in *Nature* (a scientific journal) Sir Thomas Clifford Allbutt speaks of Osler bringing to Oxford, "as gifts from the new world, an openness and simplicity of mind and conversation, a frankness and generosity of temper, a freedom from the frost and weight of custom, and a pioneer's command of affairs, which made him as delightful a fellow worker as he was clear-sighted and effectual. Oxford took him to her heart as her own; there as one of her own, he rested. And if Osler had not also to capture Great Britain, as he captured Oxford, it was because Great Britain was already his mistress. Indeed, there was not a school of medicine in the Old World where his presence was not almost as well known and his friendship as precious as in the New. It was characteristic of him that a few days later he obtained leave from Oxford to spend some months in Paris, during which he regularly attended the clinics of the great hospitals at 7:30 a. m., like an ordinary student. Of his contributions to knowledge it is as hard to make a list as it would be for Socrates. They were many, no doubt, but consisted even more in his insemination of other minds, in personal teaching and influence on his disciples. His great textbook had many and almost singular merits. It was always helpful in any quest to turn to it, because, if but in a word or the turn of a sentence one perceived that the latest and best researches, if not presented in detail, were known to the author. Thus the work was not a provider only but also to the wise an indicator. Perhaps his most original and valuable researches were in the field of the diseases of the spleen and blood; but he made eminent contributions also to the study of the infections of the heart, of angina pectoris, of malaria, and of many minor maladies. But, the most modest of men, his conversation was always of the good work of others, silent on his own."

In the *British Medical Journal*, Sir Humphrey Rolleston, president of the Royal Society of Medicine, pays a personal tribute: "Perhaps the most remarkable of his many gifts was that of rapidly making and then permanently retaining friendships. To see him speak to, and place at his ease as naturally his equal, a young man somewhat in awe of a famous leader of his profession, seemed an easy matter in his hands, and no doubt was the outcome of a wonderful sympathy that never failed, and at the same time was never

obtrusive or other than natural in a very human man. This made him the same age as his companion, and indeed, much as he loved old men, he delighted in meeting the young. To a mother in terrible distress for the loss of a son in the war he was the gentlest of comforters. In spite of his bravery he was never the same after his only son was killed. There was no trace of the wall between the generations that the years so often build up, and probably few ever realized how strange this was. His encouraging and stimulating attitude to young men made Oxford a Mecca to which there was a constant flow of pilgrims, especially from Canada and the United States, all certain of welcome. Annoyance, irritability or personal feeling of any kind was impossible to imagine in connection with his sunny temperament; that this was part of his philosophy of life is obvious in his charming address "Aequanimitas," and his attitude to his professional brethren finds expression in another address on "Unity, Peace and Concord." Though a shrewd judge of character, neither his opinion nor the reason for it, if unfavorable, was given unless there was some urgent reason, and then the man's surroundings were blamed or a semi-humorous phrase settled the question without further affecting reputation. His literary style was epigrammatic, with apt illustrations, attractive from its classical flavor, and with the distinction conferred by his easily discernable personal touch. This was the feature of his popular textbook, so remarkable for its up-to-date picture of our science. His output was enormous, and it was a puzzle how with innumerable engagements outside and an open house, very rarely without its complement of visitors, he found time to read and work. To see him examine a case was a lesson in thorough clinical observation and not least because the patient's interest was not forgotten in that of the case."

A pathetic incident is the fact that the Collection of Essays in celebration of Osler's seventieth birthday, presented by friends and pupils on both sides of the Atlantic, arrived at Oxford only two days before his death and were never seen by him. His body, which rested overnight in Christchurch Cathedral, Oxford, close by the monument of Richard Burton, one of the great dead to whom he was devoted, was brought by road to London for cremation. The family desired that the ceremony should be strictly private. Lady Osler, her sister, the late Sir William's brother, and the physicians and nurses were present. The ashes were placed in an urn and taken back to Oxford. They will probably be sent to Canada for burial, but a final decision has not yet been taken.

State Rewards for Medical Discoveries

An important report has been issued by a joint committee of the British Medical Association and of the British Science Guild, which has been considering the question of awards for medical discoveries. The committee defines medical discoveries as being: (1) the ascertainment of new facts or theorems bearing on the human body in health and on the nature, prevention, cure or mitigation of injuries and diseases; (2) the invention of new methods or instruments for the improvement of sanitary, medical and surgical practice, or of scientific and pathologic work. The reasons given for rewarding medical discoveries are the encouragement of medical investigation and the discharge of a moral obligation incurred by the public for its use of private effort. The various possible types of rewards are cited as: titles and honors given by the state, by universities and other public bodies; prizes and medals; patents; promotion and appointments; pecuniary rewards by the state. Concerning the general principle of assessment, the committee hold that, in the interests of the public, all medical discoveries should if possible receive some kind of acknowledgment or recompense. But in view of the variable conditions, nature and effects of particular investigations, it will often be difficult to assess the kind of recompense suitable. In the first place, a distinction should be drawn between compensation and reward. By compensation is meant an act of justice done to reimburse losses; by reward an act of grace in appreciation of services. The following different cases should be considered: A. Discoveries involving pecuniary or other loss either by direct monetary sacrifice or by expenditure of time, or by diminution of professional practice, without corresponding pecuniary gains. An example is that of Jenner, who occupied himself so closely with the investigation of vaccination that he lost most of his medical practice and also a considerable sum in expenses. This was fully acknowledged by Parliament, which granted him \$150,000. B. Discoveries that have increased the professional emolu-

ments of the investigator by enhanced practice or other means. Such are frequently improvements in surgical operations or medical treatment, which leads to increased practice. Another case is that of serums, etc., which may have been protected and put on the market. Here compensation cannot be demanded, and pecuniary rewards are generally unnecessary. On the other hand, honors are often and justly bestowed for such work. C. Discoveries that involve neither gain nor loss to the investigator. This class includes most of the good and sometimes great clinical, pathologic and sanitary discoveries. Here also compensation can scarcely be demanded, and honors are already often given, but pecuniary awards should sometimes be bestowed as an act of grace when the value of a discovery greatly exceeds the emoluments of the investigator. This principle should hold even for men who are directly paid for undertaking the research, especially when such payment is (as usual) small and the discovery great. Special attention is drawn to: (1) men who have refused lucrative posts to complete researches; (2) men who have refused to protect their work for fear of limiting its application, and (3) men who have carried out investigations for governments for little or no payment, on patriotic grounds.

In the public interest, the committee insists on these principles: 1. No medical discovery should be allowed to entail financial loss on him who has made it. 2. Compensation or reward should be assessed as equal to the difference between the emoluments actually received and those which a successful clinician might have received in the same time. Additional reasons for this are that few medical discoveries are patentable, and they seldom give good grounds for promotion or for administrative appointments in the public services. Whether a particular discovery shall receive large or small assessment will depend, in addition, on these considerations: 1. Width of application. For example, the work of many of the older anatomists, physiologists, and parasitologists, of Pasteur and of investigators of immunity, have affected most recent discoveries. Discoveries on widespread diseases, such as the work of Lister, Laveran or Koch, are often more important than those on more limited maladies. 2. Difficulty of the work done. The solution of a difficult problem requires more study and also more time and cost, and therefore deserves more recompense than a chance observation. 3. Immediate practical utility. A strong plea can be made for state remuneration in cases of this kind unless they come under Class B. Curiously, they never receive it, and academic recognition is also often not forthcoming. 4. Scientific importance. Discoveries not of practical utility may become so at any moment and should be included in the scheme if sound and of wide application.

During the last few years, the British government has disbursed an annual grant of about \$300,000, under the Medical Research Committee, for subsidizing investigations authorized by the committee and carried on by workers selected by it. This grant does not remunerate discoveries already made, but proceeds on the principle of payment for prospective benefits. The principle of payment for benefits already received should also be followed, as in other countries. Payment for prospective benefits is good business only when some return is almost certain. Hence subsidizing researches most frequently deal with simple and straightforward questions, admitting of immediate experimental reply. But most of the greatest medical discoveries were built on a much more speculative and uncertain basis by men who neither sought nor received subsidies—such men as Jenner, Sims, Simpson, Lister, Koch, Laveran, Bancroft, Manson, Bruce, Mackenzie. Surely the state should encourage this class of investigation also, because it costs the state nothing in the doing and seems to achieve the greatest results. This can be done only in one way—by payment. There are at present in this country hundreds of physicians and others who have the knowledge, the brains and the opportunity for private independent discovery, without subsidies, but who do not attempt it because medical research work does not pay even when brilliantly successful. They should be brought into the fold of research by the offer of a reward when they succeed.

Fatal Anthrax from Japanese Shaving Brushes

The contraction of anthrax from shaving brushes imported from Japan has been reported before in *THE JOURNAL* (Dec. 13, 1919, p. 1849). The Ministry of Health now announces that several other cases have occurred, two of which have been fatal, and that in a substantial proportion of the cases the infection was from new brushes recently imported from

Japan. The government is taking steps with regard to further importation. The ministry recommends the following process to any person who has any doubt as to a shaving brush, but does not suggest that it is a certain safeguard against infection: Thoroughly wash the hair of the brush with soap and warm water to which a little washing soda has been added, rinse in warm water, and then immerse for one hour in a solution of liquor formaldehydi. The disinfecting solution should be at a temperature slightly above the body heat. After removal the brush should be allowed to dry before use. Care should be taken not to allow the hair to come in contact with the hands.

Research Work at the Zoological Gardens

The prosectorium at the Zoological Gardens, used for research in comparative anatomy, has been reconstituted, and Professor Leiper of the London School of Tropical Medicine has been appointed director. As temporary lieutenant-colonel in the army he worked out the life history of *Bilharzia haematobia*. Since the days of Owen and Huxley the bodies of animals which die in the Zoological Gardens have been used for research in comparative anatomy. A succession of distinguished prosectors and many well known surgeons and zoologists have added to knowledge of the higher vertebrates by work at the gardens. Shortly before the war, the work was extended so as to include routine pathologic investigation into the causes of death.

PARIS

Dec. 24, 1919.

The Example Set by the United States in Matters of Hygiene

Though the war caused great sorrow and brought many afflictions, it has brought also some blessings. It facilitated the exchange of ideas between the allied nations and thus led to a better acquaintanceship and a closer union. This is particularly true with respect to the United States and France. During the progress of the war numbers of Frenchmen were put in a position to appreciate American methods and institutions. In matters of public hygiene, especially, the United States exerted a salutary influence. At the sixth annual meeting of the Société de médecine publique et de génie sanitaire, which was held recently in the Institut Pasteur, Prof. S. M. Gunn, assistant director of the Rockefeller Foundation Commission, reported the results of the hygienic crusade that was undertaken by the commission in the schools of the department of Eure-et-Loire, which followed the plan adopted for the schools of the United States. The success of this campaign has been so encouraging that the commission hopes to be able to put this branch of public health work on a permanent footing in all of France.

Similarly, various plans for reforming hygienic instruction in the medical schools owe their inspiration to the work done in the United States. For example, it is coming to be recognized that hygienic instruction must consist of two distinct stages: first, an elementary course which all students must pursue, and second, an advanced elective course for older students. Dr. Paul Courmont, professor of hygiene at the Lyons Faculty of Medicine, has already introduced these two courses. Dr. Léon Bernard, professor of hygiene at the Paris Faculty of Medicine, thinks that, following the example of the United States, a series of courses in hygiene should be established to prepare specialists in hygienic work. He advocates the following three courses: (1) a course preparing candidates for the special duties of public health officers (director of public health, state [departmental] inspector, marine public health officer); (2) a course preparing candidates for the special duties of medical inspector of schools, and (3) a course preparing for the duties of dispensary physician and director of antituberculosis sanatoriums, to be followed by a term as assistant in such establishments.

The Campaign Against Charlatanism

The Société de médecine publique et de génie sanitaire, in view of the fact that a form of charlatanism that is dangerous to public health is practiced by a number of physicians and by certain pharmacists and industrialists, has given formal expression to the opinions that it entertains in the matter: 1. Certain forms of charlatanism practiced by various doctors of medicine are detrimental to the medical profession, and for that reason it would be well to take up the matter with the Union des Syndicats médicaux. 2. The Société de médecine légale, which has appointed a

committee to study into the various forms of charlatanism in vogue, should be asked to determine just what the legal status is of certain establishments that pompously assume the name of "institutes," and certain anonymous personalities who affirm to be able to cure all diseases within an improbable time limit should also be investigated. 3. The Service de la répression des fraudes should be requested to take more energetic action against vendors of pharmaceutical products and hygienic apparatus when it can be shown that the merchandise in question is sold under false pretenses. 4. It would be well to prohibit the publication, in any journal, of advertisements of any pharmaceutical products other than those approved by a competent commission or council composed in part of members of the Syndicat des pharmaciens et des droguistes.

Ceremonies Held at the University of Paris

The council of the University of Paris has decided to hold special exercises each year in celebration of the reopening of the school. This year it was only natural that the event should take the form of memorial exercises in honor of our dead heroes. The services that the University of Paris rendered during the war were also called to mind. The ceremonies were held in the large amphitheater of the Sorbonne, at the conclusion of which the rector of the university conferred the title of doctor honoris causa on Sir Frederic Pollock, English counsellor at law; Dr. Brachet, professor at the University of Brussels; Vito Volterra, Italian senator, dean of the faculty of science in Rome; M. Nyrop, professor at the university of Copenhagen, and H. G. Greenwich, dean of the school of pharmacy in London. Previously, only one title of doctor honoris causa had been granted by the University of Paris, and was conferred last year at this time on President Wilson, by reason of his having been president of the University of Princeton.

The university has decided to hold special religious services in memory of its faculty members and its students who died for their country.

Action in Memory of the Physicians Who Died for France

At the instance of the Paris Faculty of Medicine, all faculties and schools of medicine, all medical and scientific organizations, and all student associations have decided to solicit subscriptions for a fund to be used in exalting the memory of the 1,600 physicians and medical students who died for their country. In every regional center of school or faculty, and in the principal groups of professional societies committees are to be appointed to take charge of the propaganda and to receive subscriptions.

The amount so subscribed will be used: 1. For the publication of an elaborate work containing the names of the heroes and the citations that have been accorded them; this book will be put on sale and the proceeds will revert to the subscription fund, copies of an edition de luxe being given to those who subscribe forty francs or more. 2. For the erection in Paris (near the Faculté de médecine) of a monument that shall be in keeping with the important services rendered during the war by the medical corps as a whole. An appeal is made to all French physicians, to the physicians of allied countries, to the families of these dead heroes, and to all those who, during the war, became indebted to the physicians for their life and health. Subscriptions may be sent to Dr. Bongrand, trésorier général du Comité, 6, rue Villaret-de-Joyeuse, Paris-XVII.

Marriages

CARL ASHTON BROADBENT, Lieut., M. C., U. S. Navy, to Miss Virginia Courtney Henshaw of Carolina County, Va., at Washington, January 15.

JOSEPH ANTHONY PESSOLANO, Philadelphia, to Miss Florita Marie de Dominicis of Albany, N. Y., at Philadelphia, November 19.

EDWARD H. MORIARTY, Mt. Clemens, Mich., to Miss Estella Doyle of Chatham, Ont., January 13.

SIDNEY KALLAWAY, Philadelphia, to Miss Ella M. Lee of Shامokin, Pa., December 3.

HENRY MELVIN LEE, to Miss Clara Harris, both of Minneapolis, December 27.

Deaths

John Van Rensselaer Hoff * Colonel M. C., U. S. Army (retired), Washington, D. C.; one of the most distinguished officers of the Medical Corps and leader in the movement by which the medical department became a staff corps; died in Walter Reed Hospital, Washington, D. C., January 14, after a surgical operation for septic gall bladder. Colonel Hoff was born at Mount Morris, N. Y., April 11, 1848; the son of Brevet Colonel Alexander H. Hoff, Medical Department, U. S. Army, and Eliza Van Rensselaer. He was graduated from Albany, N. Y., Medical College, in 1871, and also from the College of Physicians and Surgeons in the City of New York in 1874. In the same year he was appointed First Lieutenant and Assistant Surgeon, U. S. Army, in 1879 he was promoted to Captain, and Assistant Surgeon, and to Major and Surgeon in 1891. He organized the first detachment of the hospital corps in the Army at Fort Reno, I. T., in 1887, and the first company of instruction hospital corps, at Fort Riley, Kan., in 1891. He was also recommended for brevet and medal of honor in the Sioux Campaign in 1890 and 1891. He served through the war with Spain as chief surgeon in Porto Rico, and there organized and was president of the superior board of health and board of charities. He was chief surgeon of the China relief expedition in August, 1900. Colonel Hoff was a member of the faculty of the Army Medical School in 1901 and 1902, serving during the same period as president of the Association of Military Surgeons of the United States. In 1901 he was commissioned Lieutenant-Colonel, and Deputy Surgeon General, and in 1905, Colonel, and Assistant Surgeon General. In the latter year he was detailed as observer with the Russian Army in the Russo-Japanese War; in 1906 he was chief surgeon of the Department of Missouri, in 1907 and 1908 chief surgeon of the Philippines Division, in 1909 chief surgeon of the Department of the Lakes, and from 1910 until his retirement for age in 1912, chief surgeon of the Department of the East, and Eastern Division. Since his retirement, Colonel Hoff has lived in Washington, and for a considerable time was editor of the *Military Surgeon*.

Edward Chauncey Register, Jr., Lieut.-Col., M. C., U. S. Army; Medical College of Virginia, Richmond, 1908; aged 35; died at Tarnopol, Poland, January 3, from typhus fever. He graduated from the Army Medical School in 1911; was commissioned First Lieutenant, M. C., in the same year, promoted to Captain in 1914; to Major, May 15, 1917; and to Lieutenant-Colonel, June 12, 1918. His military service included a tour of duty in the Philippine Islands and China, and he also was a member of the punitive expedition into Mexico. In July, 1919, he was assigned to duty with the American Expeditionary Forces in France, his special work being the repatriation of German prisoners; he went to Poland in December with the American-Polish Relief Commission organized for the purpose of stamping out typhus fever, and in his letters reported a shocking and tragic condition of affairs in that area, with scarcity of fuel, clothing and food.

Frederick James Russell, Thiells, N. Y.; Tufts College Medical School, Boston, 1897; aged 46; a member of the Medical Society of the State of New York; for eight years a member of the staff of the Massachusetts School for Feeble-Minded, Waverly, then for three years superintendent of the Vermont School for Feeble-Minded, Brandon, an institution which he organized, and for the last year superintendent of Letchworth Village, Thiells; was operated on for brain tumor at the Neurological Institute, New York City, October 21, and died, December 21.

Clarence Jephtha Edwards, Abbeville, La.; University of Louisville, Ky., 1883; aged 61; a member of the Louisiana State Medical Association; for several years president of the board of health of Vermilion Parish; once a member of the state senate; for several years coroner of Vermilion Parish, and at the time of his death president of the school board of the parish; for several years editor and proprietor of the Abbeville *Meridional*, died, January 14, from heart disease.

John Robert Bosley * Lieut.-Col., M. C., U. S. Army (retired), New York City; Johns Hopkins University, Baltimore, 1901; aged 43; a graduate of the Army Medical School in 1904; who entered the Army soon after his grad-

uation and was promoted to Captain, April 23, 1908; to Major, July 1, 1916, and to Lieutenant-Colonel, May 15, 1917, and was retired, Dec. 31, 1917, on account of disability in line of duty; died, January 8, from diabetes.

Ernst Fred Tiedemann * St. Louis; Washington University, St. Louis, 1880; aged 58; associate professor of bacteriology in his alma mater; professor of pathology and bacteriology in Beaumont Medical College and Marion-Sims Medical College in 1900 and 1901; pathologist to St. Mary's Infirmary and the Jewish Hospital, and consulting pathologist to the St. Louis Mullanphy Hospital; died, January 15, from an overdose of morphin.

Michael Behrman * Visalia, Ky.; Medical College of Ohio, Cincinnati, 1903; aged 38; a member of the American Academy of Ophthalmology and Oto-Laryngology; formerly secretary of the Covington Board of Health; died in his room in the Palace Hotel, Cincinnati, January 12, from the effects of a gunshot wound of the head, believed to have been self-inflicted while he was despondent on account of illness.

Leon Brayton Harris, Saginaw, Mich.; University of Michigan, Ann Arbor, 1909; aged 33; a member of the Michigan State Medical Society; formerly coroner of Saginaw County; who was commissioned Captain, M. R. C., U. S. Army, and honorably discharged, July 14, 1919; died in the Saginaw General Hospital, January 12, after an operation for appendicitis.

James Rhines * Laurium, Mich.; Michigan College of Medicine and Surgery, Detroit, 1902; aged 42; who was commissioned First Lieut., M. R. C., U. S. Army, and was honorably discharged, Jan. 9, 1919; assistant physician to Mohawk Mining Company, and physician to Ojibwa Mining Company; died in Rochester, Minn., about January 10.

Taylor E. Raines * Concordia, Kan.; Hahnemann Medical College, Chicago, 1891; aged 67; formerly secretary and president of the state board of medical registration and examination, and president of the local board of health; one of the first health officers of Cloud County; died, January 12, from spinal disease.

Henry Josef Kreutzmann, San Francisco; University of Erlangen, Germany, 1880; aged 64; a member of the Medical Society of the State of California; formerly professor of gynecology and obstetrics in the San Francisco Polyclinic; while returning from a hunting trip, January 14, died on the train, from heart disease.

Joshua Restord Weeks, Brooklyn; University of the City of New York, 1877; aged 64; surgeon of the Second Infantry N. C. N. G. in 1877 and 1878; local surgeon of the Houston and Texas Central Railroad from 1892 to 1894; died, January 12, from cerebral hemorrhage.

Milton A. Hengst, Birdsboro, Pa.; Jefferson Medical College, 1878; aged 75; a member of the Medical Society of the State of Pennsylvania, and for ten years president of the board of health of the borough of Birdsboro; died, January 10, from cerebral hemorrhage.

Leonard Charles Mead * Yankton, S. D.; Rush Medical College, 1884; aged 63; for nearly thirty years superintendent of the State Hospital for the Insane, Yankton; a member of the American Medico-Psychological Association; died in that institution, January 10.

Frank Lawrence Cochrane * Brooklyn, N. Y.; College of Physicians and Surgeons in the City of New York, 1900; aged 44; died, January 16, from the effects of a gunshot wound of the brain, self-inflicted, it is believed, while despondent.

Charles L. Wilson, Mansfield, Mo.; Missouri Medical College, St. Louis, 1888; aged 63; for twenty-five years head of the St. John's Hospital Dispensary, St. Louis; died at the home of his sister in Santa Cruz, Calif., January 2, from cerebral hemorrhage.

John Joseph Alderson * Chicago; Northwestern University Medical School, Chicago, 1885; aged 68; once president of the West Side branch of the Chicago Medical Society; vice president of Grace Hospital; died, January 21, from rheumatic endocarditis.

Charles Albert Church * Millbury, Mass.; University of Vermont, Burlington, 1884; aged 60; while driving across the tracks of the New Haven Railroad near Northbridge, Mass., January 13, was struck by a train and almost instantly killed.

George W. Rhoads, Shelbyville, Ill.; Jefferson Medical College, 1866; aged 88; for forty-eight years a druggist of Shelbyville; a veteran of the Civil War; died, January 14.

The Propaganda for Reform

SKEEN'S STRICTURE CURE A FRAUD

Postal Authorities Deny the Use of the United States Mails to a Mail-Order Quack

For some years a concern in Cincinnati, which has gone under the names "D. A. Skeen" and "The D. A. Skeen Co." has advertised a mail-order treatment that was "guaranteed"

STRICTURE TREATMENT
Guaranteed

If suffering with Stricture, enlarged prostate, difficulty to retain or pass water, you will get immediate, entire and permanent relief by using

SKEEN'S PAINLESS REMEDY

NO CUTTING, DILATING OR DRUGGING

Use treatment 60 days. If not fully satisfied, I will return your money without complaint. No chance for you to lose a penny. My booklet, "AN HONEST TALK," with GUARANTEE, sent free—will open your eyes and convince you. Write D. A. SKEEN, Dept. 2, P. O. Box 356, Cincinnati, Ohio

Typical advertisement of the Skeen Stricture Cure.

to cure stricture or enlarged prostate. The overworked fraud-order department of the Post Office finally got around to this piece of quackery and has put it out of business by denying to the concern and its manager the use of the United States mails.

In July, 1919, George B. Poole—who was really the D. A. Skeen Co.—was called on by the federal authorities to show cause why a fraud order should not be issued against his business. When the case first came up for hearing, Poole and his attorney, Alfred G. Allen of Cincinnati, offered evidence in an attempt to defend the concern against the Government's charges. Later, Poole and his counsel, in correspondence with the federal officials, intimated that, rather than have a fraud order issued, the business would be discontinued. As a result, the Government offered to withhold further action, providing Poole would execute and file an affidavit to the effect that the business had been discontinued and would not be resumed any time in the future and that the postmaster at Cincinnati would be directed to treat all mail sent to the D. A. Skeen Co. as "refused." After leading the federal authorities to believe that this disposition of the case was desired, Poole refused to submit such an affidavit. As a result, the Government issued a fraud order against Poole and the D. A. Skeen Co.

The extracts that follow are taken from the memorandum of Judge W. H. Lamar, Solicitor for the Post Office to the Postmaster-General recommending the issuance of a fraud order.

"The scheme in substance is to falsely represent to persons that a certain treatment known as 'Skeen's Painless Remedy,' sold by respondents through the mails for use according to directions, will cure any case of Stricture or Prostate Gland trouble, and all Genito-Urinary diseases and conditions, and other serious troubles which affect persons, regardless of the cause from which the disease or diseased condition arises, their seriousness or the length of their standing; and by means of such representations and promises obtain remittances of money in payment for said

treatment. It appears from the evidence that the business done in pursuance of this scheme was started as early as 1885 by one David A. Skeen, who, according to Mr. Poole's testimony, had the treatment made up under a prescription of one of the 'oldest and best known physicians in the South,' although he could not give the name of this physician, nor was there anything in the records of respondent's business to show that they have had such a prescription. Skeen himself was not a physician and knew nothing of the cure or treatment of diseases, or the effect of drugs on the human system, but depended solely on the remedy prepared from this alleged prescription to cure some of the most serious diseases with which persons can be afflicted. Skeen died in 1914. George Poole, the present manager and principal owner of the business, settled his estate, continued the business and incorporated the same under the name The D. A. Skeen Company. George B. Poole, who is the president of this concern, is 65 years of age. He is not a physician and does not employ or consult a physician in connection with the treatment of persons who deal with him through the mails. He did not consult any competent authority to ascertain whether it was safe and legitimate to treat these various diseases and conditions before continuing the business, but in order to induce the public to take this treatment placed advertisements in a large number of papers which have a general circulation through the mails and employed literature of the most misleading character for the purpose of having persons buy the remedy."

The memorandum then quotes a number of typical advertisements used by Poole in obtaining purchasers for the Skeen "treatment." The stuff was analyzed in the Bureau of Chemistry of the Department of Agriculture and the analysis was submitted to the postal authorities in a report of Dr. Lyman F. Kebler, who has done much valuable work in aiding the Post Office in protecting the public against mail-order medical swindles. Dr. Kebler's report showed that the product was essentially a solution of ferric chlorid dissolved in alcohol and water:

Alcohol	45 per cent.
Solution of ferric chlorid	1.7 per cent.
Iron sulphate07 per cent.
Flavored with sassafras, etc.	

The memorandum continues:

"The evidence shows that this treatment consisting of one combination of drugs cannot reach and remove the serious diseased conditions which respondent urges can be

To the Medical Profession.
We can assure physicians that "Skeen's Painless Stricture Remedy" is absolutely harmless and can not possibly injure the system in any manner, shape or form. It acts on the urethra, tissue only and it does not matter in the least if it enters into the bladder.
When used according to the simple directions, it is soothing to the urethra and leaves an invigorating effect. Some of the most prominent physicians and surgeons of Cincinnati and other cities use our remedy both for themselves and their patients.

TO PHYSICIANS
An Eminent Physician's Endorsement
— of —
SKEEN'S PAINLESS STRICTURE REMEDY
From Dr. W. B. Clark, Indianapolis, Editor New York Medical Debates, (Extract).
To properly understand what constitutes

Gonorrhea.
There are but few who realize the terrible consequences of Gonorrhea if not thoroughly eradicated from the system. It not only dries up the disease, it will run into Gleet, Stricture, Rheumatism in the legs and untold misery and death. Our remedy will positively cure you, no matter how long standing your trouble. Our remedy will cure you, no matter how severe

Of course, the Skeen concern issued an advertising booklet. Here are miniature reproductions of portions of some of the pages in this booklet. The "Endorsement" of the Skeen "cure" by the "Eminent Physician" of Indianapolis occupied two pages of the booklet. We only have space for the heading.

permanently cured by the use of this remedy. The representations and promises above quoted and others appearing in respondent's advertising literature have been repeatedly shown to be false and fraudulent by the testimony of medical experts skilled in the science of the treatment of diseases and diseased conditions who have frequently been called upon to testify in similar medical mail order cases before the Post Office Department, and such testimony was adduced in this case and is a matter of record herein. This testimony was given by highly experienced and well qualified physicians and is based not only upon their actual experience in the treatment of these diseases, but also upon certain well established physiological, anatomical and therapeutical facts with which they are familiar. The testimony shows that each of the numerous diseases and diseased conditions treated by these respondents with this one remedy may arise from many and varied causes, and in order to successfully treat such diseases and diseased conditions it is necessary first to ascertain the cause or causes thereof, and then

intelligently apply a suitable treatment which will reach and remove such cause or causes, and in order to effect a cure the superinducing cause must be found and treated, that different causes often require different treatment and that no one treatment can or will cure all cases, and might not cure any."

Judge Lamar then quotes the evidence of the witnesses called by the Government in the case and concludes:

"This and other testimony in the case very clearly indicates the falsity of the representations made by these respondents in order to market their treatment. It leaves no doubt as to the inability of the remedy to relieve and cure the various diseases and diseased conditions for which it is recommended. It shows that these conditions in question may arise from various causes each of which may require for its removal different treatment; that none of the drugs which compose the treatment used, either separately or in combination can, unless by chance, reach and remove the principal cause which produces the condition, and hence cannot effect the promised cure. The return of the postmaster at Cincinnati, Ohio, shows that about the time of the issuance of the citation in this case from 15 to 20 pieces of mail were received daily at that office addressed to The D. A. Skeen Company and delivered.

"I find that this is a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises, and I therefore recommend that a fraud order be issued against The D. A. Skeen Company, and G. B. Poole, Manager, at Box 356, and 22 Opera Place, Cincinnati, Ohio."

The fraud order was issued December 3, 1919.

Correspondence

"HIGH PROTEIN DIETS AND NEPHRITIS"

To the Editor:—In THE JOURNAL, January 10, p. 107, the following editorial statements appear under the above title:

"We may accept these observations . . . without admitting their wider significance in the etiology of human nephritis. . . . It must be remembered that the diets used by Newburgh were potentially acid in character, and certain to produce an acid urine in a species adjusted and accustomed to secrete an alkaline fluid under a free choice of food. Until such experiments are successfully duplicated under conditions in which the normal reaction of the renal secretion is not tremendously altered and the accessory factors in the diet are known to be adequate, the incrimination of the high protein diets in connection with nephritis must be considered with judicial reserve."

The writer of the editorial refuses to admit that the experiments in question bear on the problem of the cause of human nephritis because the renal injury might, in his opinion, have been produced by the acid character of the diets or by the absence of some essential food factor.

Neither of these objections is justified by the facts. Even though the writer of the editorial states that the diets were certain to produce an acid urine, the data show that such was not the case. A careful review of my notes discloses the fact that, without exception, the urines of the rabbits eating both the casein mixture and the soy bean diet were alkaline to litmus.

The second objection offered implies that the nephritis might be an expression of a deficiency disease. Here, again, a "judicial consideration" of the data will show that such a view is untenable. In the case of the casein experiments it will be noted that two groups of animals were used. Each group was fed a diet made up of a mixture of milk, water and carrot, to which casein was added. The first group of rabbits received 15 gm. of casein daily in this way; the second group, 30 gm. The first group failed to develop nephritis. How, then, can the nephritis which was found in the second group be attributed to a lack of something in the diet, when the latter group received everything which the first group did, and in addition, fifteen more grams of casein daily?

When we come to the soy bean experiments we also find sufficient evidence to prove that the nephritis was not caused by the absence of something in the food. The investigators who have made a special study of the vitamin content of foods have compared the growth curve of animals eating foods whose vitamin content was to be tested, with the normal growth curve. On the basis of such studies, a food which permits normal growth is accepted as one whose vitamin content is adequate. In the soy bean experiments, two groups of young animals were used. One group was used as a control; the other group was fed the beans. All other conditions were identical for the two groups. The controls, after living on the stock laboratory diet for seven months, had an average individual weight of 2,415 gm. Their kidneys were normal. The group of young animals eating soy beans averaged 2,179 gm. at the beginning of the experiment. Three months later, their average individual weight was 2,497 gm. Still another group of rabbits eating soy beans weighed 2,382 gm. at the beginning of the experiment and 2,780 gm. three months later. The animals living on soy beans gained weight at more than the normal rate in both instances. Evidently, then, the nephritis produced by the soy beans cannot be attributed to a lack of something in the diet.

L. H. NEWBURGH, M.D., Ann Arbor, Mich.

"THE ACUTE ABDOMEN"

To the Editor:—Anent the controversy of your correspondents (Dr. M. W. Lyon, Jr., THE JOURNAL, Dec. 20, 1919, p. 1897, and Dr. Ramsay Spillman's rejoinder, Jan. 3, 1920, p. 47) will you please allot me some of the valuable space of THE JOURNAL to shed additional light on the moot point, "acute abdomen."

I want to call attention to the fact that William Henry Battle, senior surgeon to St. Thomas Hospital, London, whose name is identified with the incision so extensively employed in operations for appendicitis, delivered an oration before the Medical Society of London, ten years ago, entitled "The Acute Abdomen." Under this very caption, "The Acute Abdomen," the first edition of his monograph, 250 pages, appeared, dedicated to students and surgical dressers, which, having been exhausted in 1914, went into a second edition.

Perusal of this book, "The Acute Abdomen," which bids fair to become a classic, might answer the hypercritical Dr. Lyon, and perhaps explain to Dr. Spillman the *fons et origo* of the purity of the terminology. "The Acute Abdomen," which he credits to Dr. Gibson.

Comment of the editor has it that "scientific medicine demands scientific phraseology." Be that as it may, there is also an art of medicine to be considered; and to give expression thereto, it is meet to draw such metaphor as "the acute abdomen," which visualizes a clinical picture, the syndrome of which is common to a host of acute ailments peculiar to the abdomen. As for terminology—the essence alike of science and art—both are daily enriched by new coined words. Thereafter, common usage is authority for their sanction and thereby establishes its precedence over pedantry. Why muse with Homer or risk being judged hypercritical, when browsing amid the bookshelves of a modern library would have led "to pastures new"—"The Acute Abdomen" of ten years' growth.

MARTIN W. WARE, M.D., New York.

"STANDARDIZATION OF LABORATORY TESTS"

To the Editor:—Reference to the standardization of the Wassermann test was made in two recent numbers of THE JOURNAL (Dec. 6, 1919, p. 1773, and Dec. 20, 1919, p. 1897). In neither of these was mention made of research work which is now being conducted at the University of Pennsylvania and the Polyclinic in Philadelphia under the direction of John A. Kolmer, and which represents, no doubt, the best attempt which has as yet been made to standardize this important test. The results of this work will, I am informed, appear in a series of about twenty papers in the

American Journal of Syphilis. The first two articles of this series were published in the January, 1919, number of that journal. To date, six papers have appeared. It is expected that the balance will appear during the course of this year. All laboratory workers who make the Wassermann test will be greatly interested in the results obtained by the Philadelphia investigators.

HENRY ALBERT, M.D., Iowa City.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

"PNEUMO-STREP-SERUM"

To the Editor:—Mulford & Co. are advertising a serum called pneumo-strep-serum, one of their advertisements appearing in the *Journal of the American Public Health Association* for January, 1920. Is there really anything in the claims which they put forth in this advertisement which should lead men to use a combined serum of this kind? A hasty reading of this advertisement by medical men would induce them to believe that this serum was the very mithridate of pneumonia.

Your opinion of the subject will be thankfully received.

GEORGE W. GOLER, M.D.,
Health Officer, Rochester, N. Y.

ANSWER.—This advertisement is in the form of an announcement, with large head lines "Announcing the Production of Pneumo-Strep-Serum." It informs the physician that reports from army camps indicate that various streptococci are frequently associated with pneumococci as causative factors in pneumonia. The advertisement features a picture showing the method of injecting cultures into a serum-producing horse. It suggests to the physician that "when it is determined that the pneumonia is complicated by the streptococcus, the conjoint use of Antipneumococcic Serum Polyvalent and Antistreptococcic Serum Polyvalent is indicated." The advertisement then goes on to say that "the difficulties and inconvenience of separate injections" may be avoided by the use of this new preparation, which is prepared "by injecting horses simultaneously with the fixed types I, II and III of pneumococcus, also some strains from group IV pneumococcus, and 15 key strains of streptococcus." This serum, the manufacturer says, "therefore possesses the combined advantages of antipneumococcic and antistreptococcic serums." It is also claimed that "it contains antibodies against all the various strains of pneumococcus and streptococcus employed." Finally, it is stated that "by standardization against type I pneumococcus, it is equally as potent against type I pneumonia as the type I and polyvalent antipneumococcic serums."

The advertisement by going beyond our present knowledge carries misleading inferences, a few of which may be mentioned. It takes for granted that the therapeutic value of antipneumococcus and antistreptococcus serums is settled. The fact is that the different varieties of such serums are still in the experimental stage. The serum against pneumococcus type I has received perhaps the most favorable comments, but available evidence based on the experience in the army camps during the war does not leave a very large margin on which to predicate any claims for effective specific action even by this serum. Of the other serums of the class mentioned in the advertisement not one warrants the inferential claim of specific value. Again, the advertisement conveys the impression that pneumonia generally is a mixed infection, but that is not the case, especially when it concerns the classical lobar pneumonia caused by some variety of the pneumococcus, and, after all, that is the kind that the physician is called on most frequently to treat. The advertisement assumes a power of antibody-production by the horse that has not been demonstrated. Fundamental facts in immunology indicate that a horse injected with so great a variety of antigens is not able freely to produce all the corresponding antibodies. Even if the serum of horses injected with a single variety of pneumococcus or streptococcus can acquire specific therapeutic value in human infections with that organism—which has not been demon-

strated conclusively—there nevertheless would be little chance that a horse injected simultaneously with the fixed types one, two and three of pneumococcus, also some strains from group four pneumococcus and "15 key strains" (whatever that may mean) of streptococci could yield a serum of such manifold specific virtues as inferred by the advertisement.

The basic question involved in the inquiry is whether or not the medical profession should take its therapeutics from the manufacturers of therapeutic products. The medical profession has, for its own protection and information, created a body that is competent to determine the probable scientific value of therapeutic agents. That body is the Council on Pharmacy and Chemistry. Had the "Pneumo-Strep-Serum" of Mulford's the virtues with which the advertisement inferentially endows it, this product would have been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Nonofficial Remedies. It has not been so accepted although many other biologic products of the same manufacturer have been. It is to be regretted that such journals as the *American Journal of Public Health*, *Military Surgeon*, *Southern Medical Journal*, *Journal of Laboratory and Clinical Medicine*—among many others—should permit the use of their pages for such purposes when they could easily protect themselves and their readers by securing accurate information concerning such products from the Council on Pharmacy and Chemistry. If there is one field in which reliable information and unprejudiced scientific opinion should prevail it is in the therapeutics of biologic products. At the present time, too many manufacturers are advertising these products without any regard for scientific fact or rationality, and too many physicians accept therapeutic instruction concerning these products from those commercially interested.

Miscellany

THE PHYSICIAN AND THE PROHIBITION LAW

Internal Revenue Regulations 60, regulating the manufacture, sale, transportation, importation, exportation, delivery, purchase, possession and use of intoxicating liquor under the national prohibition act providing for the enforcement of the eighteenth amendment of the constitution, have just been issued by the commissioner of internal revenue.

Previous regulations provided for the enforcement of the war time prohibition law.¹

LIQUOR DEFINED

Liquor is defined to include alcohol, whisky, brandy, rum, gin, beer, ale, porter and wine, and, in addition, any spirituous, vinous, malt or fermented liquors, whether medicated, proprietary, patented or by whatever name called, containing one-half of one per cent. or more of alcohol by volume, which are fit for use for beverage purposes. This definition includes homeopathic potencies, attenuations and dilutions. It does not include denatured alcohol or denatured rum or medicinal and other alcoholic preparations unfit for use as beverages.

PHYSICIAN DEFINED

The word "physician" is defined as meaning any person duly licensed to practice medicine and actively engaged in the practice of medicine in the state in which licensed. It does not include osteopaths and chiropractors. Pharmacists are any persons licensed under the laws of any state to compound and dispense medicines prescribed by a duly licensed physician and who are actively engaged in the practice of such profession.

CONDITIONS UNDER WHICH LIQUORS MAY BE USED

Under the conditions provided, intoxicating liquors may be made, transported, sold and used in the manufacture of medicinal preparations in accordance with the formulas prescribed by the U. S. Pharmacopeia, National Formulary,

1. THE JOURNAL A. M. A., Jan. 19, 1918, p. 186; Feb. 9, 1918, p. 410; March 2, 1918, p. 645; July 5, 1919, p. 121; Oct. 4, 1919, p. 1080; Oct. 25, 1919, p. 1304; Nov. 15, 1919, p. 1544.

or the American Institute of Homeopathy, which are unfit for use for beverage purposes:

1. In the manufacture of patented, proprietary and other medicines which are unfit for use for beverage purposes.
2. By retail druggists and pharmacists in the compounding of medicinal preparations unfit for use for beverage purposes, and for dispensing on physicians' prescriptions.
3. By physicians in the practice of their profession.
4. By hospitals and sanatoriums for medicinal and scientific purposes.
5. In manufacturing industrial establishments for first aid treatment.

Alcohol may be used for medication by druggists or pharmacists for laboratory purposes, by dentists and veterinarians in the course of their practice, and by any college, university or institution of learning in any laboratory for scientific research, and in any hospital or sanatorium.

Alcoholic medicinal preparations fit for use as beverages may be used by retail druggists in compounding prescriptions of physicians, by hospitals and sanatoriums for medicinal purposes, and by physicians in the practice of their profession.

WHO MAY SECURE PERMITS

All persons desiring to manufacture, sell, furnish, prescribe, purchase, possess or use intoxicating liquor must procure permits. Persons procuring liquor for medicinal purposes on prescription of physicians holding permits to prescribe are not required to have a permit themselves. Permits to prescribe intoxicating liquor do not confer authority other than to prescribe, that is, a physician holding a permit to prescribe liquor for his patients in his practice is not authorized thereby to manufacture or sell intoxicating liquors.

APPLICATIONS FOR PERMITS

Applications for permits must be made on Form 1404, in triplicate. All three copies must be signed by the applicant, the original being sworn to before a notary public. All three copies must then be forwarded to the federal prohibition director in charge of the administration of the law in the state. The director may issue a permit, such permit being in triplicate, and having the same serial number as the application. One copy of the permit and the application are returned to the applicant.

Full names must be signed to each application. The permit when granted must be conveniently and permanently filed so that it is readily accessible at any time. Any person holding a permit, who moves his place of business (as a physician changing his location) may surrender his copy of application and permit to the director and have a new one issued with the change of location.

Permits issued prior to Jan. 17, 1920, must be renewed as the commissioner may direct, but holders of such permits may continue to operate under them until their new applications are acted on.

Permits issued prior to August 31 of any year will expire on December 31 of that year.

BONDS

Bonds in duplicate must be filed with the application, except that unless otherwise required by the commissioner, no bonds need be filed by physicians, dentists or veterinarians asking for permits to use intoxicating liquor in the course of their practice, or hospitals and sanatoriums.

DELIVERY OF LIQUOR

Whisky and brandy, bottled in bond, for medicinal purposes may be delivered on receipt of permits on form 1410 to hospitals or sanatoriums or to physicians holding permits to purchase liquors for medicinal purposes, or to wholesale or retail druggists or pharmacists.

PERMITS TO PURCHASE

Any person entitled to procure intoxicating liquor must submit an application to purchase on Form 1410. This application, when approved by the director, becomes a permit. The applicant must describe the intoxicating liquor in detail, and must give the quantity in gallons of each kind of intoxicating liquor on hand at the time of the application and the quantity in gallons previously received by him during the current calendar year. The application must also show

the name and address of the vender, the purpose for which the liquor is to be used, the serial number of the permit held by the applicant, and the address covered thereby. All applications must be sworn to and must be made in triplicate. If transportation is required, one or two additional copies must be made. All copies are forwarded to the director for approval. All permits to purchase expire in ninety days after the date of approval.

HOMEOPATHIC AND ECLECTIC PHYSICIANS

Physicians of the homeopathic and eclectic schools, after obtaining a permit to use alcohol or homeopathic potencies, attenuations and dilutions in the course of their practice, may procure such preparations from homeopathic pharmacists. One month prior to the current quarter of the calendar year, each homeopathic or eclectic physician may file an application on Form 1410 in triplicate, for the total quantity of alcohol or homeopathic potencies, attenuations and dilutions which he desires to purchase during the following quarter. This application, when approved, becomes a blanket permit to purchase goods for ninety days. It must state the name of the homeopathic pharmacist from whom the physician desires to purchase these preparations. No physician may receive in excess of 15 gallons of alcohol or alcoholic preparations during any one year.

U. S. P. AND N. F. PREPARATIONS

Distilled spirits and wines may be used in the manufacture of medicinal preparations in accordance with U. S. Pharmacopeia and National Formulary or the American Institute of Homeopathy, provided they are unfit for beverage purposes. They must contain no more alcohol than is necessary, and must contain in each fluidounce a dose of recognized therapeutic value.

Preparations included in the U. S. Pharmacopeia and National Formulary which are fit for beverage purposes will be regarded as intoxicating liquor and subject to the same restrictions.

DENATURED ALCOHOL

Alcohol may be denatured by any one of the following seven formulas:

1. Mercuric chlorid, 1:2 000; mercuric chlorid, 0.8 gm.
2. Hydrochloric acid, 60 c.c.; alcohol, 64 c.c.; water, 300 c.c.
3. Mercuric chlorid, 1½ grains; hydrochloric acid, 2 drams; alcohol, 4 ounces.
4. Formaldehyd, 2 parts; glycerin, 2 parts; alcohol, 96 parts.
5. Phenol (carbolic acid), 1 dram; tannic acid, 1 dram; alcohol, 1 pint; water, 1 pint.
6. Alum, ½ ounce; formaldehyd, 2 drams; camphor, 1 ounce; alcohol and water, 1 pint.
7. Liquor cresolis compositus (U. S. P.) 10 c.c.; alcohol, 1,000 c.c.

SALE OF DENATURED ALCOHOL

Retail druggists may sell alcohol medicated as above in quantities not to exceed one pint for other than internal use, without physicians' prescriptions, to persons not holding permits, provided that in each case the container bears a poison label. Alcoholic medicinal preparations, not for use for beverage purposes, may be sold by retail druggists on physician's prescription, provided the name of the druggist appears on the prescription in the physician's handwriting. Prescriptions may not be issued for more than one pint of such liquors at any one time. Refilling of such prescriptions is forbidden. Pharmacists may refuse to fill such prescriptions if they have reason to believe that physicians are prescribing for other than medicinal purposes or that a patient is securing, through one or more physicians, quantities of intoxicating liquor in excess of the amount necessary for medicinal purposes, which shall not be more than one pint to the same person in ten days. Physicians may not prescribe liquor for their own personal use.

PRESCRIPTIONS FOR LIQUOR

Pharmacists filling prescriptions for intoxicating liquor must, at the time of filling, endorse on each prescription, over their signature, the word "cancelled," together with the date on which the liquor is delivered. Such prescriptions must be kept in a separate file. Once a month each druggist must send to the director a list of prescriptions filled by

them, showing the names of the physicians, the names of the patients, and the total of liquor dispensed to each patient during the month. Retail druggists selling intoxicating liquors, whether on a physician's prescription or otherwise, must pay special tax as liquor dealers and must keep such tax stamp conspicuously posted.

ADMINISTRATION OF LIQUOR BY PHYSICIANS

Distilled spirits, wines and alcoholic medicinal preparations fit for use for beverage purposes may be administered by physicians to their patients for medicinal purposes, when such liquor is necessary to afford relief for some known ailment, and when delay in procuring the liquor through a retail pharmacist on prescription might result in loss of life, aggravation of the ailment, or intense suffering. Physicians may obtain no more than six quarts of liquor during any calendar year to be administered to their patients only in quantities necessary to afford relief at the time of administration. They may not sell or furnish such liquors to any persons. The total amount of liquor administered to any one patient by one or more physicians may not exceed one pint in ten days.

HOSPITALS AND SANATORIUMS

Persons conducting bona fide hospitals or sanatoriums, engaging in the treatment of persons suffering from recognized disease or ailments (except treatment of alcoholism), may administer liquors to patients in necessary quantities on prescription of the hospital or sanatorium physician. Such physician shall issue a separate prescription for each patient, but a separate prescription for each dose is not necessary unless prescribed at irregular intervals. All such prescriptions must be in duplicate, both copies signed by the physician, and must show the name of the hospital or sanatorium, the date of issue, the name of the patient, the kind of liquor prescribed, the directions for use, and the amount to be administered during any given period.

ALCOHOL FOR EXTERNAL USE

Tax paid alcohol procured by hospitals or sanatoriums may be issued to attendants for rubbing purposes on prescriptions issued by the hospital physician. Denatured alcohol may be issued to attendants in quantities not exceeding one pint, without a prescription.

HOSPITAL REPORTS

Hospitals or sanatoriums must report at the end of each month to the director, sending one copy of each prescription, and must keep the other copy filed chronologically at the hospital. Hospitals or sanatoriums are forbidden to sell or furnish liquors or alcohol to other persons.

INSTITUTIONS FOR ALCOHOLICS

Bona fide hospitals or sanatoriums engaged in the treatment of alcoholism may obtain liquors and alcoholic medicinal preparations for use in the treatment of chronic alcoholism, but only when the tapering off method is used, or when the dosage is steadily reduced until the patient, within a reasonable time, such as four weeks, has lost the craving for alcoholic stimulants. Such liquor may be administered to patients only in necessary quantities and only under the direction of a duly qualified physician employed by the hospital. Such institutions must keep three records, the first containing the name and residence of the patient, age, date of entry and departure from the institution, and the condition for which he is treated. A serial number will be given to each patient when admitted. The second record will show the serial number of the patient, condition for which treated and the amount of liquor furnished him during the period treated. A copy of this record will be forwarded to the director each month, the serial number being used in place of the name of the patient. The third will show the quantity and kind of liquor on hand the first of each month, the quantity received during the month, the quantity dispensed to patients, the quantity used in compounding legitimate medicinal preparations, and the quantity on hand at the end of the month. A transcript of this record will be sent to the director each month.

USE OF LIQUORS IN EMERGENCIES

Intoxicating liquors may be administered in case of accident, shock or other emergency, only by a physician, nurse or other person in charge of first aid stations in manufacturing, industrial and other establishments. Such establishments must keep a record in duplicate, and must transmit a copy each month, showing the amount on hand, the amount received and the amount dispensed, with the date and the name of each person to whom dispensed and the amount on hand at the end of the month.

DENTISTS

Dentists may use alcohol for professional purposes in quantities not to exceed six quarts a year. Applications for permits to use alcohol for such purposes must state the purposes for which it is intended.

LABORATORIES

Alcohol may be used for legitimate laboratory purposes, such as chemical, biologic, bacteriologic and clinical, provided its use is nonbeverage, and that it is of such a nature as effectually to preclude diversion of the alcohol for unauthorized purposes. Applications for permits from laboratories will be treated separately on their merits on account of the varied nature and multiplicity of such laboratories.

PRESCRIBING OF LIQUOR BY PHYSICIANS

Physicians who have filed applications on Form 1404 and who obtain permits to prescribe intoxicating liquor may prescribe such liquors for persons on whom they are in attendance, if, after careful physical examination, or in cases in which such examination is impracticable on the best information obtainable, the physician believes that the internal or external use of such liquor as a medicine is necessary, and will afford relief from some known ailment.

No prescription may be for more than is necessary for the person for whom it is prescribed, and in no case shall it exceed one pint in ten days for the same person by one or more physicians.

Physicians are not permitted to write prescriptions for liquor for their own use, or to use any liquor procured on prescriptions written by them. Prescriptions may be filled only by a pharmacist and may not be refilled.

PRESCRIPTION BLANKS

All prescriptions must be made on Form 1403, and must contain all the data called for. If the physician does not possess any such forms, and delay may result in loss of life or intense suffering, he may prescribe without the use of Form 1403, but his prescription must contain all the information called for. Blank prescriptions on Form 1403, issued by the commissioner in book form, serially numbered, may be procured without cost by any physician holding a permit. Not more than one book shall be issued to a physician at a time.

Prescription blanks are printed with stubs attached, the stub being a duplicate. All prescriptions must be in duplicate, both copies signed by the physician. After the last blank has been used, the book containing the duplicates must be returned to the director. Any unused, mutilated or defaced blanks must be returned with the book.

In case of prescriptions written on other forms in an emergency, duplicate copies must be returned to the director at the end of the month. Prescription blanks must be used in the order of the serial numbers printed thereon.

PHYSICIANS' RECORDS

Physicians prescribing intoxicating liquors must keep on Form 1402 an alphabetical record showing every such prescription issued by him, giving the date, the amount and kind of liquor prescribed, the name of the patient, the ailment for which prescribed, the directions, and the amount and frequency of the doses.

LIABILITY

No special liability is incurred by physicians, hospitals or sanatoriums for special tax for administering intoxicating liquors in cases of emergency.

THE HOUSE OF CALVARY HOSPITAL

ROBERT J. REILEY
Architect
NEW YORK

The House of Calvary Hospital is devoted to the care and treatment of men and women suffering from cancer and is in charge of Catholic sisters of the Dominican order. The hospital was located for many years in Perry Street, New York; but when this property was taken by the city in connection with the opening of a new street, it was decided to move to a less congested portion of the city and to erect a building to accommodate about eighty patients. The new site was selected with regard to the importance of having light and air on every side and at the same time of being readily accessible from the center of the city by the existing lines of transportation.

The management desired to maintain as far as possible the atmosphere of the home about the hospital, and this

Fig. 1.—House of Calvary Hospital.

influenced the architect to select the colonial style of architecture, as it is probably more typical of our American home life than any other. The building is laid out on what is known as the pavilion plan, that is to say, the main wards are located in wings connected with a central building. In this case the pavilions are placed at right angles to the central building so that they may run approximately north and south, in order to obtain both morning and afternoon sun in all of the main wards. At the south end of each pavilion is a solarium for the patients occupying that ward, and at the north end an open balcony for use according to weather conditions.

Figure 2 shows the arrangement of rooms and wards on the main floor. The second floor is similar in general arrangement and is devoted to women patients. The third floor contains in the easterly end of the building the roentgen-ray room and the surgical department, comprising a seven bed ward, and sterilizing, wash up, etherizing, operating and recovery rooms. The westerly wing is devoted to the sisters' apartments, and in the central part of the building are a few private rooms for women patients. Owing to the

Fig. 2.—First floor plan.

special character of the work of this hospital, a room for changing dressings is placed on each floor and a small gas incinerator is part of its equipment.

The building is constructed of fireproof materials throughout; the columns, floor beams and girders are of steel, the floor construction of concrete, and the partitions of terra cotta blocks. Not only is the building itself fireproof, but an effort has been made to eliminate the danger from a fire in the contents of the building. This danger is that of smoke, and more particularly the panic caused by the smell of smoke. With this in mind, each floor of the building has been subdivided, and the passage of smoke from one floor to another has been prevented by enclosing the stairs and elevator shafts. On once entering the stair enclosure on any floor one may proceed downstairs and out of the building without reentering any of the corridors, thus insuring a smoke free exit.

One of the problems encountered in hospital construction has been the difficulty of obtaining a satisfactory material for use on the floor. In this case, in the wards and corridors it was decided to use linoleum cemented to the concrete underflooring with an interlining of felt. This material has many points to commend it, as it is sanitary, noiseless, and comfortable; but it is necessary to have the concrete thoroughly dried out before it is laid and to equip the beds and other heavy furniture with large feet or casters. Tile floors are used in the operating, sterilizing and etherizing rooms and in the toilet rooms; wood floors in the reception room, office and nurses' rooms, and cement floors, treated to prevent powdering or dusting, in the service portions of the hospital.

The building is heated by hot water; but an auxiliary steam heating system was installed so as to provide a means of rapidly heating the operating room, especially in the spring and fall when the general heating plant might not be in operation. This system also supplies steam for the laundry and sterilizing rooms. While natural ventilation is made use of as far as possible, artificial ventilation has also been installed. The building is cleaned by means of a stationary

vacuum cleaning plant placed in the basement but controlled from every floor. An electric push button is located beside each bed to light the nurses' signal, the elevator and dumb waiters are electrically controlled, and in general all practical labor saving devices have been adopted.

477 Fifth Avenue.

Texas June Examination

Dr. M. F. Bettencourt, secretary of the Texas State Board of Medical Examiners, reports the written examination held at Austin, June 24-26, 1919. The examination covered 12 subjects and included 120 questions. An average of 75 per cent. was required to pass. Of the 82 candidates examined, 80 passed and 2 failed. One hundred and thirty-one candidates, including 1 nongraduate and 32 osteopaths, received physicians' and surgeons' licenses by reciprocity. The following colleges were represented:

Illinois June Examination

Mr. F. C. Dodds, superintendent of registration, Illinois Department of Registration and Education, reports the written and practical examination held at Chicago, June 16-20, 1919. The examination covered 10 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 226 candidates examined, 201 passed and 25 failed. Twenty-six candidates were licensed by reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	No. Licensed
University of Colorado	1	(1913)	1
Chicago College of Medicine and Surgery	3	(1916), (1917, 3)	4
Chicago Hospital College of Medicine	11	(1918)	11

Iowa September Examination

Dr. Guilford H. Sumner, secretary of the Iowa State Board of Medical Examiners, reports the written examination held at Des Moines, Sept. 16-18, 1919. The examination covered 8 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 12 candidates examined, 11 passed and 1 failed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Loyola University	88.7	(1919)	88.7

Book Notices

ON GUNSHOT INJURIES TO THE BLOOD-VESSELS. FOUNDED ON EXPERIENCE GAINED IN FRANCE DURING THE GREAT WAR, 1914-1918. By George Henry Makins, G.C.M.G., C.B., President of the Royal College of Surgeons of England. Cloth. Price, \$5.50. Pp. 251, with 64 illustrations. New York: William Wood & Co., 1919.

This book presents, first, reports on the primary treatment of wounds by various surgeons working at the casualty clearing stations in the British Army, and, secondly, a series of case reports collected from hospitals on the lines of communication and during a service of five months at a base hospital in London. The author discusses several of the important conditions affecting the frequency of injuries to blood vessels. He states that the existence of a contusion of the arterial wall is not readily determined in the absence of ocular demonstration, as obliteration of the peripheral pulse may equally denote a contused lateral wound, complete severance or, as shown by explorations, no appreciable lesion at all. He recommends Bayliss' 6 per cent. gum arabic solution except in very acute hemorrhage, in which case he advises whole blood to replace the blood lost. Observations are presented which oppose the view that actual dilatation of the heart may be present in subjects of arterial wounds. Rather a want of tone in the heart muscle accounts for the outward displacement of the cardiac apex. This condition, Makins states, is similar to that observed in the unwounded at the front and diagnosed "disordered action of the heart." Pronounced cardiac systolic murmurs were observed frequently in thirty-seven out of 180 cases of arterial lesions. Eighteen were arteriovenous, and nineteen pure arterial wounds. The development of arterial hematoma and the various kinds of aneurysms and aneurysmal varix are described in detail. The author says that patients who have suffered a recent hemorrhage should not be operated on; while they may seem to be in good condition, they may fail to recover from the anesthetic and die within a few hours. Local anesthesia and careful hemostasis are indicated. Operation was of value when vasomotor and secretory disturbances were present. Mobilization of the nerve trunks accompanies operation, as it prevents secondary vascular changes in many cases. Observations tend to show that trophic changes are due not to vascular injury alone but to associated nerve injury. One new practical point which has been proved in this series is that the vein also should be ligated, following ligation of a main artery. To leave the vein viable diminishes the residual blood pressure maintained by the collateral circulation, and predisposes to gangrene. When suture is impossible in a main artery, the circulation may be maintained by means of a Tuffier tube, which may be gradually obliterated by a blood clot, giving the collateral circulation a chance to become enlarged. Much better results were obtained from the treatment of blood vessel injuries after ligation of both artery and vein and improved initial treatment of the wound. The result of injuries of the blood vessels illustrates the sinister influence of interference with the blood supply to a part on the development of anaerobic gangrene. The reader will be disappointed by the lack of emphasis on operative technic, and the absence of detailed description. The review of the cases illustrates the difficulty of following up cases in the army, and shows the necessity for a better system of postoperative observations.

Medicolegal

Liability for Erysipelas—Touching Reputation

(*Hanson v. Thelan* (N. D.), 173 N. W. R. 457)

The Supreme Court of North Dakota, in affirming a judgment for \$300 damages in favor of the plaintiff, says that he, a boy 16 years old, sustained a fracture of his right leg between the knee and the ankle. Both bones were fractured. The boy was placed in a hospital under the care and in charge of the defendant. There was some testimony in the record that for about three days the defendant applied ice packs to reduce the swelling. Then he set the bones and enclosed the leg and foot in a plaster cast. The boy complained of suffering pain, and in about a week the cast was cut open and the leg was tightly bandaged with cloths. Three weeks later these bandages were taken off, and a board was placed under the leg and foot; they were wrapped in bandages, and a weight and pulley were attached. About two weeks after that these appliances were removed, and a shoe was laced on tightly, next to the bare foot, with some cotton batting inserted, and a weight and pulley were attached. Prior to the attaching of the last mentioned appliances, there were sores or bruises on the foot. Some two weeks later, the shoe was removed, after the boy had complained of suffering, and the foot was then black and blue. Three days after that the defendant put some salve on these sores. A physician from Bismarck came and examined the boy, and stated that erysipelas might be expected. The boy became quite ill, and was removed to a hospital at Bismarck, where erysipelas developed, and where he became very ill for many days, and remained for seven weeks. The main question in the record was whether the erysipelas developed from the method of treatment accorded by the defendant, and whether the defendant was derelict in his duty in that regard. The defendant contended that the evidence was insufficient to warrant the verdict for the reason that there was no direct evidence in the record that the condition of erysipelas was brought on the plaintiff by any act or omission of the defendant; also that the plaintiff by his own conduct in going out when the fracture was mending contrary to the instructions of the defendant, and otherwise disobeying instructions given by the defendant, precluded any recovery.

The law is now well settled that the physician owes to his patient the duty to exercise reasonable and ordinary care, diligence and skill such as are ordinarily possessed by physicians practicing in similar localities in the same general line of practice. It is equally well settled that the patient must not have contributed to his injury in any degree; that he must conform to all reasonable directions of his physician—otherwise he cannot recover. In other words, in an action against a physician for breach of his professional duty to his patient, the patient cannot recover if he has not conformed to all reasonable directions of his physician, or if his conduct has contributed to the injury on which the action is based. Under the evidence in this case, the court is of the opinion that the question of the defendant's negligence and of the plaintiff's contributory negligence were fairly questions for the jury. With reference to the contention that there was no direct or positive evidence to show that the resulting erysipelas was proximately caused by the acts of the defendant, the court is satisfied from a consideration of the testimony of the laymen, in connection with the expert testimony of two physicians for the plaintiff, that there was no error in submitting the question of the defendant's negligence to the jury. There was some evidence that the manner in which the shoe was bound to the foot was not proper, and that it was not examined sufficiently regularly or often, although the expert evidence in this regard was not strong.

The defendant asserted that his good reputation as a physician was at stake, and that this court should not condemn him as an incompetent or careless practitioner, on the record herein. It does not follow that this judgment so rendered, or its affirmance, does so condemn the defendant. Surely

physicians and surgeons are liable to make mistakes and to err in the performance of their duty to the patient occasionally, just the same as any other profession or any other trade. For a physician or a surgeon to assert that he is infallible and never makes a mistake is to place his ability and learning above the usual and ordinary run of human experience.

Recovery Allowed for Professional Services

(*Brooks v. Aldrich et al.* (R. I.), 107 Atl. R. 100)

The Supreme Court of Rhode Island, in overruling the defendants' exceptions and remitting this case with instructions to enter judgment on a verdict for \$4,000 in favor of the plaintiff, says that the action was brought by the plaintiff against the executors under the will of one Benedict to recover for personal services alleged to have been rendered to Mr. Benedict at his home and at the plaintiff's office daily, including week days and Sundays, day and night, for medicines, medical advice, and for treatment by the plaintiff's assistant and under his direction, by electric massage, etc., during the period from Sept. 1, 1909, to April 20, 1915, exclusive of the months of July and August in each year; also for services rendered during July and August, 1912, in going to Europe at the request of Mr. Benedict and there performing services of the same nature, and \$1,500 for expenses actually incurred by the plaintiff on that trip; the total amount due the plaintiff being alleged to be \$13,150 and interest. Mr. Benedict was a bachelor, who died in April, 1915, at about the age of 78. The plaintiff was a physician who specialized in treatment by electricity, Swedish movement and massage. For many years he had been an intimate friend of Mr. Benedict, and had treated him for various troubles during that time, or up to 1899, when the plaintiff moved to New York State, but testified that he returned in 1909 at the request of Mr. Benedict, for the purpose of taking care professionally of the latter during the remainder of his life. Mr. Benedict having promised, if he would do so, to provide generously for the plaintiff in his will. As no legacy was left to the plaintiff by Mr. Benedict, this suit was brought to recover from Mr. Benedict's estate for the value of the services rendered to him. The trial of the case required eight days, and the defendants in presenting their defense were properly allowed considerable latitude in the presentation of testimony. The defense was a denial of the amount and value of the services claimed to have been rendered, and payment. Prior to 1899, when the plaintiff moved away, Mr. Benedict paid him usually each month for services rendered. From 1909 until the death of Mr. Benedict there was much evidence to support the plaintiff's claim of a different arrangement. During this period the plaintiff rendered professional services to Mr. Benedict. No charge was made on his books therefor, and the defendants, although it appeared that Mr. Benedict was a man of very careful business habits, were able to produce but two receipts for small amounts showing payments to the plaintiff. Without referring in detail to the testimony, there was sufficient evidence, if believed by the jury, to warrant the verdict. The substance of one group of the defendants' exceptions was objection to the testimony of the plaintiff as to the reasonable value of his services; but the defendants took nothing by these exceptions. The plaintiff was qualified to give his expert opinion, and the fact that he was an interested party had a bearing on the weight to be given to his testimony, but not on its admissibility.

Suicide as Evidence of Insanity

(*Wallace v. United Order of Golden Cross (Me.)*, 106 Atl. R. 713)

The Supreme Judicial Court of Maine says that the presumption of sanity must be entertained in the absence of proof, and when the record is silent. This presumption is not overthrown by the act of committing suicide. Suicide may be used as evidence of insanity, but, standing alone, it is insufficient to establish it. Insanity cannot be predicated simply on the act of self-destruction; for human experience has shown that sane men have taken their own lives.

Killing of Insured Physician on National Guard Duty

(*Interstate Business Men's Accident Association of Des Moines, Iowa, v. Lester* (U. S.), 257 Fed. R. 225)

The United States Circuit Court of Appeals, Eighth Circuit, in affirming a judgment in favor of Mrs. Lester for the full amount of an accident insurance policy issued by the defendant association on the life of her husband, says that the policy insured him "while he is engaged in the occupation of a physician and surgeon . . . in case of death effected directly and independently of any other contributing, concurring or intervening cause, by external violent and accidental means." When the insurance was taken out, in January, 1913, and at the time of his death, Dr. Lester was engaged in the practice of his profession at Walsenburg, Colo. He was also a member of the national guard of that state, holding the rank of major, and assigned to the medical corps. When the governor called the national guard into service during the strike of the employees of the Colorado Fuel & Iron Company, Dr. Lester joined his company as a part of its medical corps. On the morning of April 29, 1914, he visited a number of his patients in Walsenburg, professionally. He then went with a small detachment to a point a few hundred yards from the city; the force having been sent out to reconnoiter and resist, if necessary, the activities of strikers who were in the foothills or mountains near the town. The lieutenant of this force was wounded. Dr. Lester had just finished dressing his wound, and was down on his hands and knees in a railroad cut observing some men through his field glass, to decide whether they were strikers or soldiers. He was shot, and died almost instantly. Was he at the time of his death "engaged in the occupation of a physician and surgeon"? Was his death effected wholly by "accidental means"? This action on the insurance policy turned wholly on these two questions, which are answered in the affirmative. The defendant insisted that the language of the policy, when fairly interpreted, confined Dr. Lester to the practice of his profession in the ordinary walks of civil life; that, when he joined his company in the military service to which it was called, he changed his vocation and become, instead of a physician and surgeon, a soldier; but the court does not think this position could be sustained without disregarding the facts. His service with his company was temporary. He was called out to meet an emergency. While the service lasted for some months, it was a side issue. It was known that it would be temporary, and was to be considered as answering a call to suppress a riot, or any other temporary engagement. This measured the term of the service; but the court must look at the character of the service also. Dr. Lester was in no way engaged in the military activities of his company. His services were those of a physician and surgeon. He continued to practice his profession at Walsenburg, as well as attend to the needs of his company. The authorities are uniform that such temporary changes do not constitute a change of occupation within the meaning of insurance policies. To constitute such a change there must be an abandonment of the vocation specified in the policy and the adoption of some other calling. If such temporary activities are to destroy the protection of insurance, it must be by an express provision in the policy. So far as vocation is a factor in determining the hazard, it is based on the average of the whole class. A physician practicing his profession in the congested districts of a large city will be exposed to many hazards to which a physician in a small country town will not be subject. All of these matters, however, are embraced in the general average of hazards of the class of physicians and surgeons. If one individual at one time is exposed to a largely increased hazard, as Dr. Lester was on the occasion of his death, others will be exposed to hazards falling greatly below the average. These are factors on which the insurance is based. Nor is it true that simply going into an environment of greatly increased hazard, with conscious knowledge of such hazard, will cause injury or death which results therefrom not to be accidental within the meaning of such policies as this one.

Social Medicine and Medical Economics

ADVERTISING IN RURAL PUBLIC HEALTH WORK

An Account of Some Methods Used Successfully in Lee County, Mississippi

CHAILLOS CROSS, M.D.

State Director of Rural Sanitation, Mississippi State Board
of Health

GEORGE G. HAMPTON, M.D. (Senior Field Director of Rural Sanitation,
Mississippi State Board of Health); FRED C. CALDWELL, S.B.,
M.D. (Senior Field Director, International Health
Board), and CLARKE H. YEAGER, M.D. (Senior Field
Director, International Health Board)
TUPELO, MISS.

Preventive medicine has been given a tremendous impetus by the experiences of the late war; but if work of this nature is not pushed energetically while the interest still lives, the old apathy will return. Public health work is a business and will yield the greatest results if business

25,000 people. Most of the county seats are cities of from 3,000 to 10,000, and the other communities vary in size from a mere cluster of houses to towns of 800 inhabitants. The population is about evenly divided between white and black.

Individualism is strong among the white population, for there have been no foreign accretions, at least since the Civil War. The native American cannot be coerced. Any change from the old customs and habits of life demanded by outside authority constitutes for him a violation of personal rights and liberty. When the national government first enforced the laws to protect the cattle against the Texas fever, several of the dipping vats in this county were dynamited. But once convinced, the native American becomes a willing co-worker. He can be more easily led if the natural leader of his community is first persuaded. These strategic men usually live in the towns, where most of the progressive people are to be found. Between these towns there is often jealous rivalry, but a community or county spirit has never been well developed.

Public health work in this state had its inception ten years ago and is still in its infancy, although developing rapidly.

Exhibit at fair.

methods are used. This applies equally well to the internal organization and to the means used to secure public cooperation, without which the work is impossible. Various forms of public health work have been carried on long enough to develop good internal organization and to construct excellent programs, but these often fail in securing their maximum success because public sentiment is not behind them.

In the ordinary lines of business it is well known that many firms which manufacture a superior line of goods never grow, while others whose products are no better, or even of inferior quality, have an enormous development, owing to the wise and extensive use of advertising. In this way the public is informed of the particular merits of the firm's goods, and a demand for them is created even in the most remote communities. With this idea in mind, the Department of Rural Sanitation of the Mississippi Board of Health decided to use advertising methods in its health campaign in Lee County.

To be successful, the methods employed in advertising must be adapted to the people whom it is desired to reach. Mississippi is essentially a rural state with a population of approximately 2,000,000 and with no city of more than

It remained for us to plan in Lee County a campaign that would educate the people along health lines, and at the same time develop a community and county spirit, which are telling, or even indispensable, factors in developing permanent health work. A county with a boosting spirit will not permit disease to run unchecked after the first enthusiasm of a health campaign has died down. The program which we outlined to the progressive business and professional men of the county at once won their backing.

As in every other community, the finances were not unlimited, and every dollar had to be stretched to the utmost. The methods employed in the campaign were adaptations of means used in other lines of business to interest prospective customers and make them buy. From the first, we let no opportunity slip to bring our work to the attention of the people. Articles were written for the local newspapers, attractive signs were placed in prominent places, and stereomotorgraphs showing pictures of our work were placed in conspicuous positions in the windows of business houses in Tupelo, the county seat and headquarters of our organization. The arrival of a circus in the city afforded an excellent opportunity for publicity, for, without any expense, we

were able to place a sign on one of the elephants, advertising our work. Though utilizing every opportunity that thus presented itself, in carrying forward our campaign we relied mainly on our original advertising devices, a description of which may prove interesting.

Advertising the health campaign at the circus.

THE PUBLIC MEETINGS

As would naturally be expected in a community of intense individualism, we encountered serious opposition when we

began our work in the county. Petitions were circulated against us in every district. We wanted the people to feel that we were really their friends and not the representatives of some unknown arbitrary force that had come to change their methods of living. We knew that nothing could be more potent in overcoming their distrust and suspicion than

well planned public meetings, in which the people might become acquainted with the workers and the work that was being done.

The ordinary public health meeting is not exceedingly popular. We therefore decided to use moving pictures to secure larger crowds to whom we could explain the advantages of the sanitary measures we were advocating. The films were used simply as a means of entertainment and not necessarily to teach health subjects, although we realize that a moving picture that will educate, and at the same time furnish enjoyment, would be the ideal. Such films are rare, but in the near future we shall be able to describe one that we are now producing.

A Delco representative readily consented to furnish the lighting system, the moving picture projector, and films if we would pay only the return charges on the films. Inasmuch as the lighting system was mounted on a Ford truck, we were able to hold such meetings in the most remote communities. A phonograph, which a local dealer lent to us, was also a part of our equipment. In the course of time we found it to our advantage to arrange for a supply of films from a film exchange in a neighboring city, and to use a truck belonging to the state board of health and equipped with a Delco system.

The results were remarkable, for instead of scant crowds, our audiences varied from 100 to 500 in size. Several times the crowd was so large that we were compelled to hold the meeting outdoors. But the most pleasing result to us was the changed attitude of the people toward us throughout the county. It was necessary only to announce in a church or school that one of our meetings was to be held, and the place of meeting was filled at the appointed hour.

BULLETINS AND HEALTH SEALS

Intensive health work is necessarily a slow process, and in a county of 28,000 people several months must elapse before every home is surveyed. In order to stimulate interest and promote health education in every home in the county

Mile post sign.

throughout the progress of our work, a weekly bulletin was published and widely distributed in the county.

Another type of bulletin was published monthly for distribution throughout the state. This was a challenge to citizens of other counties to awake to the necessity for health campaigns in their communities, such as is now in progress in Lee County.

One of the health posters of the American Medical Association has been adapted to local conditions, and a seal

printed to be used on all mail of the department of rural sanitation. The state board of health, several of the Mississippi schools, and some of the local business men have agreed to use them on all of their correspondence.

Both of these means of advertising have a double purpose, for in addition to keeping interest alive in Lee County, they have been useful in arousing the interest of other counties in public health work.

Warning at approach to curve.

EXHIBITS AT LEE COUNTY FAIR AND STATE HEALTH OFFICERS' MEETING

At the Lee County fair, although our booth was located on the second floor among the educational displays, it was visited by more people than any other one exhibit. The bare walls of the booth were covered with white cloth, and ferns, green trimmings and a phonograph added to the attractiveness of the display.

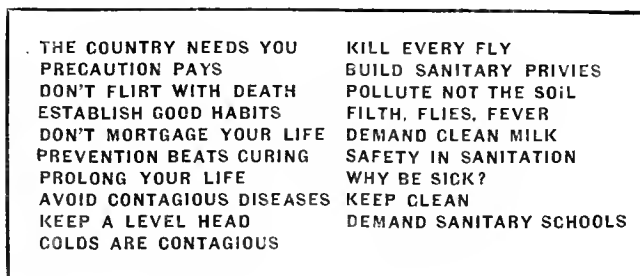

The visitor was shown first the living hookworm under the microscope and then the two sources of human infection, polluted soil and vegetables. Two bottles of milk, one infected with typhoid bacilli and the other pure, were shown to demonstrate that there is no apparent difference caused by this dangerous contamination. The fact that both typhoid fever and hookworm disease are spread by the careless disposal of human excreta was forcibly explained, and then the sanitary privy that we were advocating was demonstrated. Infant welfare and malarial charts formed part of the exhibit. On leaving, the visitor was given literature and asked to register so that we might send him further information concerning the progress of the work. More than 8,000 visitors came into the booth. The register showed that these people came from seven different counties. Demands have since come to us for the same type of campaign in several of the neighboring counties.

During the state health officers' meeting at Jackson, a similar exhibit was demonstrated. Several new features were added, among them a miniature section of Lee County, showing the road signs, next to be described, and an educational feature illustrating the equipment which we take to our community meetings in the county. This exhibit received favorable comment from men prominent in health work throughout the United States, and has endeared us to the people of Lee County.

THE MILE POST SIGNS

A design for a mile post sign was prepared, such as the one in the illustration, with a top board for advertising the

county as a model health county and giving the number of miles to the cities on that road, and featuring a health sentence. On the lower part of the sign there is space for two business advertisements. The design with specifications was submitted to various sign painters for bids, and the lowest bidder secured the contract. The plan was then placed before the business men with a price for advertisements such that the cost of the two would just cover the cost of the sign. They grasped the idea so eagerly that we soon had demands enough to place a sign on every mile of road in the county and to place a warning sign on both approaches to every dangerous turn. We were compelled to turn some advertisers away.

A few of the sentences used on danger signs.

Once the idea and its significance were appreciated by the people of the county, we had no trouble at all in persuading the chamber of commerce to place an arch over each entrance to the county. On one side of the arch were the words "Welcome to Lee County, the model health county" and on the other "Come again to Lee County, the model health county." The chamber of commerce also agreed to place sixty signs at important cross roads to explain why the health campaign was in progress in the county.

To increase the public interest in these signs a contest was held to secure the best possible health sentences for

A sign at an important cross road.

the mile posts. The business men were approached and readily agreed to furnish the three necessary prizes. Sentences were received from men, women and children from one end of the county to the other. Incidentally, it may be of interest to note that the first prize was won by the daughter of the first man in the county to complete the needed sanitary improvements on his premises.

By means of these signs we have not only boosted county pride and spirit, aided visitors, and advertised our merchants,

but through the old familiar didactic method of repetition we have driven home to the people of the county the need for, and the methods of, preventing disease. The whole county looks on the signs as a county effort, and the health campaign as its own.

RESULTS OF PUBLICITY

In a county which was originally hostile to our work, with the exception of a few progressive citizens in the city of Tupelo, we have in three months been able to accomplish the following:

1. To make a health survey of 2,712 homes, learn the diseases with which they have been afflicted during the last five years, and locate each accurately on a health map of the county so that future work will be more easy.
2. To examine 8,907 people for hookworm and furnish treatment to each person found infected.
3. To construct 827 sanitary privies, which will minimize the spread of filth diseases.
4. To distribute more than 30,000 pieces of literature.
5. To vaccinate 200 people against typhoid.
6. To make 600 inspections of business houses.
7. To make complete physical examinations of 1,100 school-children.
8. To control an epidemic of scarlet fever.
9. To contribute to the county a vision of what may be accomplished by community effort.
10. To secure cooperation of the public such that a permanent department of health can and will be established next year.

CONCLUSIONS

1. Advertising is an American method and wins Americans.
2. Advertising is invaluable in rural public health work.
3. Carefully planned advertising can be carried on at practically no expense to the health officials.
4. Such methods produce the maximum results in securing the backing of business men.
5. Wise advertising educates the community along health lines.
6. Such advertising as we have described unifies a community and gives it an aggressive spirit.
7. It can be done.

AN EARLY VENTURE IN INTESTINAL SURGERY

The modern surgeon who is inclined to note with pride the achievements in his field perhaps does not realize that even some of its most technical developments were duplicated long ago. Frederick Smith, in his work 'The Early History of Veterinary Literature and Its British Development,' quotes a statement by Harward, made in 1673, concerning the repair of intestinal wounds:

"Then if there be any torn along the guts, or else jagged, that may not be stitched together for it will not grow, neither will that which is black, cold, and dead, in which case thou must do this. First, lay the two broken ends that should grow together the one a little over the other in your hand; then cut them both off at once with a pair of scissors, so that the new cut ends may be joined close together, but first cut the two broken ends off close to the mid-rise (mesentery) and cast them away, then with a fine needle and thread, or silk, stitch the two cut ends together so that they may gently meet and not be strained. Begin first to stitch at the mid-rise (mesentery) and round about the gut till you come to the same place again and then make fast your thread. But in this stitching remember this that as you must not draw your seam too hard for fear of crushing that tender skin, neither must you leave it too slack for fear the dung issue out, for if you miss either way you are sure to fail in your cure. When you have stitched the gut ends together with a fine and thick (close) seam and wiped away the blood and dirt clean, then anoint it with hog's grease and the juice of Comfrey mixed. This done put the guts into the belly and stitch up the breach, first the inner side (peritoneum) then the middle (muscles) and then dress with moulten butter

and stitch up the outermost skin as is taught before, and use the beast as in the former cure, only do this more, that is, give him the juice of Comfrey in strong ale or beer to drink, and if he dung and stink in two or three days, there is no doubt of the cure. But in both these cures be sure of good help and be quick at thy work and be careful withal."

Surgical Barrage.—This paper was abstracted in THE JOURNAL, Oct. 18, 1919, p. 1238.

Advantages of Nitrous Oxid-Oxygen in Labor.—Having used this analgesic for some years, Turner offers five good reasons for its value: 1. The entire second stage is practically painless. 2. There is no exhaustion. 3. The postpartum psychoses are greatly lessened. 4. There are fewer lacerations of the mother's soft parts, especially of the perineum. 5. Healthy babies are delivered. Convalescence is rapid; this, of course, depends to some extent on the nature of the delivery. Involution takes place promptly, and the patient's recovery is uneventful. The function of the breasts is not disturbed by the use of gas-oxygen. Ordinarily the patient takes gas-oxygen very readily. The uterine contractions push the head farther and farther down into and through the pelvis, and it is finally born without much pain. In fact,

labor is in all respects normal. As a rule, the multipara, who has experienced the older methods of delivery, is better satisfied when delivered with the aid of gas-oxygen.

Prophylaxis of Gestation.—This paper was abstracted in *THE JOURNAL*, Oct. 25, 1919, p. 1307.

Effect of Low Oxygen on Respiratory Volume.—The respiratory volumes of twenty-nine men during the reduction of oxygen tension by rebreathing and during short exposures to constant low oxygen tension following the period of rebreathing were studied by Ellis in connection with the sea level respiratory volumes. An increase in the respiratory volume was noted at the end of the fifth minute of rebreathing, at an average of 18.1 per cent. oxygen (approximately equivalent to 4,000 feet altitude) in twenty-three of the twenty-nine subjects. The respiratory volume during the first ten minutes of the exposure to constant low oxygen tension, varying from 5,000 to 21,000 feet equivalent altitude, was greater than the sea level volume in thirty-two of the thirty-six subjects. The respiratory volume of seventeen of the thirty-six subjects fell during the first ten minutes of the exposure to constant low oxygen tension to a volume lower than that moved during the reduction of oxygen by rebreathing although still greater than the sea level respiratory volume. This fall in respiratory volume during the first ten minutes of exposure to constant low oxygen tensions was correlated apparently with compensations to low oxygen advantageous to the subject. The return to sea level oxygen tension was followed by a prompt return to the sea level respiratory volume.

Alveolar Air and Respiratory Volume at Low Oxygen.—Twenty-four men were taken to 352 mm. pressure in a low pressure chamber at a rate equivalent to an ascent of 1,000 feet per minute. In these cases the average alveolar oxygen tension fell 66 per cent. and the alveolar carbon dioxide fell 24 per cent. The average carbon dioxide tension was definitely lowered at 656 mm. (4,000 feet) which indicates that the onset of increased breathing had occurred. The lowest

carbon dioxide tension occurred about five minutes after 380 mm. was reached, when the reduction was equivalent to an ascent of 1,000 feet per minute. Both oxygen and carbon dioxide alveolar tensions responded quickly to rapid successive reductions of barometric pressure to 428 mm.

Reaction of Medullary Centers to Low Oxygen.—According to Lutz and Schneider the cardiac and respiratory medullary centers in man respond quickly to changes in the partial pressure of oxygen. A decrease in oxygen stimulates while an increase in oxygen inhibits the action of these centers.

Experimental Studies on Ureter Contractions.—The experiments reported on by Satani showed that distention of the ureter lumen causes the development of contractions, which increase to a certain limit with an increase in pressure. The chemical composition of the kidney secretion may also effect the development of ureteral contractions by means of a reflex action. The viscosity of the fluids which pass through the ureter lumen affects the contractions only to the slightest degree. Solid bodies, such as a calculus, however, produce vigorous tonic contractions. Satani concludes that the peristalsis of the ureter should be referred not to one, but to several factors, which act mainly in cooperation, but which vary in value under various conditions.

Increase in Intracranial Pressure in Rabbits.—Increasing the intracranial pressure in rabbits 20 mm. of mercury (272 mm. of water) or more, Moore says, results in accelerated respiratory movements followed by their cessation, slow heart beat, vasoconstriction, dilatation of the pupils, spasms of asphyxiation, and finally death within from one to three minutes unless artificial respiration is used or the pressure is released. Moderate degrees of pressure, 15 mm. of mercury (200 mm. of water) or less, cause increase in the rate of heart beat, vasoconstriction and a rise in body temperature. The pressure symptoms and death following "heat puncture" operations were found only when an opening was left in the cranium; and, by comparison with the symptoms attending artificially increased intracranial pressure and clinical cases of brain lesions, seem to be due to the same cause. The cause of death, and the preceding symptoms, when the intracranial pressure is raised, appears to be stimulation followed by paralysis of the principal bulbar centers.

Infra-Red Radiant Energy and Eye.—The work reported on by Luckiesh was prompted by the recently developed opinion that eye glasses, especially in the industries, should not transmit infra-red radiation. The data presented in this paper do not directly reach the root of the problem but they are of considerable importance. Energy quantities and densities in the eye mediums are established and should aid the physiologist who is interested in the question. This paper is confined purely to the physical aspects of spectral energy distribution in illuminants, of the absorption by the eye mediums, of optical laws, of luminous efficiency of illuminants, etc.

Action of Suprarenal Secretion.—Results reported by Cannon present the first indication that under quiet, peaceful conditions there is no suprarenal secretion or a secretion so slight as not to affect the denervated heart, an extremely sensitive indicator. These observations prove that suprarenal secretion is not a necessity, at least in times of serene existence. Adrenin is secreted, however, in times of great emotional stress and under circumstances which cause pain or asphyxia. The function of the suprarenal medulla is to be looked for under conditions which rouse it to action. Excitement, pain or asphyxia are self-preservation. Under such circumstances, as has been emphasized in the presentation of the emergency theory, the operation of the sympathetic division of the autonomic system together with the aid which adrenin affords will muster the resources of the organism in such a way as to be of greatest service to such organs as are absolutely essential for combat, flight or pursuit. It appears, therefore, that the emergency theory of the suprarenal medulla is the only one which thus far has any experimental support.

Result of Treatment of Neurosyphilis.—A review four years or more after the dismissal from the hospital of ten cases of neurosyphilis who were reported as aided by anti-syphilitic treatment is made by Solomon. Nine of these patients were committed as insane, the remaining case was diagnosed general paralysis but not necessarily committable. Eight cases were diagnosed general paralysis, two as cerebrospinal syphilis. The diagnosis of cerebrospinal syphilis was changed from general paralysis in one of these two cases only because the case cleared up under antisyphilitic treatment. The mental symptoms were those of paresis. Of the eight cases diagnosed general paralysis, five patients are now living at home. Three are apparently entirely well; two, while not well, are able to care for themselves and live a normal life in the community. Two are dead and one is in a hospital. One of the two who died had a fair remission with economic efficiency for eighteen months and had all laboratory reactions negative at one time. The one who was in a hospital had a remission of three years' duration. Two cases were diagnosed cerebrospinal syphilis (nonparetic); but with marked mental symptoms. One patient left the hospital apparently entirely normal and with negative laboratory signs. He has been lost from view. The other is now serologically negative and mentally normal after four years. Of eight cases diagnosed general paralysis, three patients are apparently entirely well after four years; two are well enough to live outside and care for themselves; one had a remission of more than three years' duration, and is now in a hospital; two are dead, having had a remission of eighteen months each. Of two cases diagnosed cerebrospinal syphilis with mental symptoms, one patient is lost from observation, the other is mentally normal and serologically negative. This report leads the author to feel that it is possible to render help in a portion of cases of general paralysis or cerebrospinal syphilis with mental symptoms, and that intensive, systematic treatment will change the prognosis of general paralysis.

- Time Element in Reconstructive Surgery. R. W. Johnson, Jr., Baltimore.—p. 33.

Anatomy of Snapping Hip.—A clinical study of two cases convinced Jones that the structure which infringes on the trochanter and causes the snap is the tendon developed on the deep surface of the gluteus maximus muscle. This tendon constitutes the insertion of the gluteus maximus to the gluteal ridge of the femur and it was apparent that in the two cases studied the tendon was in an abnormal state of development. That the tendon was the offending structure in these two cases was confirmed by the fact that stitching it down to the whole length of the great trochanter put a stop to the production of the snap.

Stripping of Os Calcis.—The operation which Steindler first described in 1917 consists mainly in the subperiosteal stripping of the muscular attachments to the anterior surface of the os calcis. The operation does not intend to do more than to free a muscle bound claw foot or hollow foot from the strain of contracted musculature of the sole of the foot. Any deformity arising from abnormalities of the skeleton must be taken care of by additional bone operation. In some cases this operation had to be accompanied by osteotomy of the tarsus in order to overcome the cavus deformity of the skeleton. In a series of other cases dropping of the first metatarsal and retraction of the big toe was overcome by Sherman's procedure, that is, by severing the extensor of the big toe beyond the metacarpal phalangeal joint and fastening the tendon to a point proximal to the head of the first metatarsal.

Physical Examination of Applicants for Industrial Positions.—Of 300 applicants examined by Scheffel fifty-one presented gross defects. Among these were: enlarged inguinal glands, 13 cases; heart murmurs, 4 cases; ankylosed finger joints, 5 cases; partially amputated fingers, 8 cases; destroyed tendon function, 3 cases; defective vision, 11 cases. In addition to these defects there were thirty-three applicants who had been in this country from four to eleven years who could not read the English alphabet to have their eyes tested by the ordinary Snellen's test type. The scope of these examinations extended from head to foot in a general way, but record was kept only of those defects related to the performance of the duty required of the applicant in case he was accepted for employment. The mentality of all applicants was carefully surveyed with the view of eliminating feeble-minded, imbecile and degenerate types. None was found in this series of examinations.

Serum Treatment of Epidemic Poliomyelitis.—Among the eighty-five cases of epidemic poliomyelitis which occurred in Dubuque, ten patients died, a mortality of 12 per cent. Seventeen were not treated with Rosenow's serum; of these eight died, a mortality of 47 per cent. Sixty-eight patients were treated with the serum, and of these two died, a mortality of 3 per cent. In the two fatal cases conditions were such that curative effects of the serum could not be expected. The ages of the patients ranged from 2 weeks to 18 years. The average age of the untreated group was 4.8 years, and the average age of those treated was 4.7 years. The great majority of patients in each group were less than 6 years of age. The disease was about evenly distributed between boys and girls. There was no lull in the epidemic between the treated and untreated groups. The crest of the wave of the epidemic occurred seven days after the serum treatment was begun. There was no difference in the severity of the early symptoms in the two groups of cases. The differences in mortality and incapacity would seem, therefore, in Rowan's opinion to be attributable to the good effects of the serum.

Cholera Carrier Problem.—The researches of Schöbl and of Panganiban on cholera carriers in guinea-pigs have shown that food plays an important rôle in the appearance and the disappearance of the vibrios in the feces. The normal period for recovery of the cholera vibrios from artificially infected guinea-pigs has been definitely established to be approximately fourteen days, after which time they can no longer be found. In Bilibid prison, the cholera carriers were given hexamethylenamin and, following Schöbl's experiments with ox bile in guinea-pigs, 0.65 c.c. of ox bile, three times a day, for two days; after an interval of five days the treatment was repeated. Those persons negative after the treatment were released from quarantine. Inspissated beef bile was used. It was not supposed that the bile would cure the carrier condition, but that it would cause more vibrios to enter the intestinal tract from the gallbladder.

Cystolithiasis with Dietetic Deficiency.—The results of Padua's investigation show that a relation apparently exists between the general dietetic inadequacy and deficiency among Filipinos and the incidence of phosphatic calculi, in contrast with the reported predominance of uric acid and urate calculi in Europe and in the United States. Of ten cases of cystolithiasis which he particularly studied since this investigation was undertaken, nine patients not only gave a history of having had beriberi, but exhibited actual signs referable to the disease. Although the clinical data of all but two of the other forty-eight cases are, as a whole, obscure with respect to the history of nutritional disease, still they indicate that the majority of the patients were undernourished and underdeveloped.

 Simultaneous Fluoroscopy in Two Planes. H. C. Gage.—p. 230.

An Inherited Abnormality.—Oddie's patient, a boy aged 14 years, had one-jointed fingers on both hands. His mother had similar hands, and four of her nine children were similarly affected, the other five being normal.

Unusual Fracture of Os Calcis.—Glasson's patient had a fracture of the upper and posterior surface of the os calcis with displacement of the fragment, the forward end to the inner side. There was a transverse oblique fracture from the anterior portion to just in front of the posterior third of the upper surface, with dislocation forward of the lower segment. The tendo Achilles was not broken through, though some strands attached to the upper and posterior point of the os calcis were broken, lifting the fractured piece upward.

 *Normal and Morbid Conditions of Testes from Birth to Old Age in One Hundred Asylum and Hospital Cases. F. W. Mott.—p. 737.
 *Mumps in Adults. G. MacLeod.—p. 742.

Normal and Morbid Conditions of Testes.—Mott examined postmortem an emulsion of the brains of a successive series of 100 cases of general paralysis of the insane by dark-ground illumination, and found the spirochete present in 66 per cent. His assistant, Mr. Geary, examined by dark-

ground illumination the seminal fluid obtained postmortem from the vesiculæ seminales of fifty cases of general paralysis, also an emulsion of the testicles; spirochetes were not once seen. This result, Mott says, indicated that the seminal fluid of a paralytic is, in all probability, noninfective at the time he is suffering with this disease. The family history of fifty-four male tabetic or taboparalytic patients showed that they had 151 children alive, seventy-five who were born alive but died in early infancy, and fifty-two born dead or miscarriages. This offered a striking contrast to the family history of twenty-five female tabetic or taboparalytic patients, ten of whom were sterile; the remaining fifteen had ten children alive, ten who were born alive but died in infancy, and fifty-one miscarriages or stillbirths. In the latter case both father and mother were syphilitic, and in the former the father in most instances married when the spirochete was no longer circulating in the lymph stream of the body, but was confined to the specially closed lymphatic system of the brain and spinal cord, the periaventricular sheath of the vessels and perineuronal spaces which contain the cerebrospinal fluid. Mott also makes a detailed report of the results of the examination of the development of the testis from birth to puberty; normal spermatogenesis in cases of death from shock caused by severe injuries; the testes of a large number of general paralytics, of twenty-two cases of dementia praecox and of six cases of imbecility and idiocy.

Mumps in Adults.—Among the 694 cases of mumps in adults, analyzed by Macleod, orchitis has been the most frequent complication occurring in 140, or 20 per cent., of the cases. Relapses were met with in seventeen cases. All the above cases were in adult males from 18 to 40 years of age; seventeen were second attacks and one man claimed to have celebrated his third attack.

Tick Fever in Palestine. F. D. Nicholson.—p. 811

*Erythema Nodosum and Tuberculosis. E. Ward.—p. 811.

Chronic Intestinal Stasis in Children.—In discussing the treatment of this condition, Taunton says, that in children prevention should be the first aim. The maintenance of the correct posture comes before all else. Should there be at any time from any cause a tendency for the symmetrical posture of rest to be assumed it must be checked. Rest, physical exercises, tonics, change of air, must all have their appropriate use. When stasis already exists, and the symptoms of autointoxication are recognized, should careful examination point to a congenital cause, such as an appendical control, an operation is called for. There should be no delay; the earlier it is done the less will development be interfered with by the toxemia, the less risk will there be of an acute attack of appendicitis intervening prior to the operation, the more easy will it be to break the habit of absorbing poison which the bowel has acquired, and the fewer adventitious bands and membranes will have formed in conjunction with this form of control. In the acquired form operative interference should be avoided, if possible, but each case must be judged on its merits. Nasal obstruction must be dealt with, and a free airway established through the nose. Liquid petrolatum should be given before each meal to act as a lubricant and render the passage of the food more easy. Opening medicine, in the form of aperients, purgatives, cathartics, etc., should be avoided, except in the form of an occasional dose for some special reason. Agar-agar mixed with semisolid food is useful when the point of stasis originates at the sigmoid, and is most marked there. An abdominal support which keeps out of the pelvis the sagged portions of the bowel in which stasis exists is of the greatest use. An hour's rest in the recumbent position in the middle of the day will often help in a wonderful manner. Should these means fail or not suffice after due trial, operative measures will be necessary.

However successfully the bowel has been freed from all controls, means must be taken to prevent the original cause or causes from becoming operative again. Attention must be paid to the nonoperative treatment where indicated, and always liquid petrolatum should be given for from six months to a year. Those portions of the bowel where stasis existed will tolerate delay from custom, and, having acquired the habit of absorption, both the custom and the habit have to be broken; in the same way, after the enucleation of tonsils and removal of adenoids, it is necessary to break the habit of mouth breathing, and unless that is done nasal breathing will not be resumed although the airway is patent.

Erythema Nodosum and Tuberculosis.—Although Ward does not suggest that tuberculosis is the only cause of erythema nodosum, he points out that a similar cutaneous manifestation may be due to many different poisons, one of which is that of tuberculosis. Moreover, the constitutional peculiarity which gives rise to this skin reaction seems to be inherited, as are other peculiarities—such, for instance, as the well known disposition to epidermolysis bullosa after slight injuries. Out of 4,000 cases of tuberculosis and contacts under annual observation, Ward has not yet noticed any other skin condition (apart from the well recognized tuberculides) which is definitely connected with tuberculosis. It has been stated that lupus erythematosus is attributable to tuberculosis, and Ward has seen a few cases of this disease, but not more than would be accounted for by coincidence; not more, for instance, than the cases of lichen ruber planus, which no one suggests is due to tuberculosis.

Pregnancy Complicated by Volvulus of Pelvic Colon. V. Bonney and E. C. Bridges.—p. 846.

Apparent Spontaneous Rupture of Spleen.—Shorten reports the case of a soldier, aged 43 years, who while walking was seized with pain in the region of the umbilicus, so severe that it caused him to fall to the ground. He vomited, and the pain subsided sufficiently to allow him to walk to his billet. He endeavored to carry on his duties, which were light, but the pain became worse. His medical officer came to the conclusion he had colic and gave him a dose of castor oil, which he immediately vomited. As the pain was getting steadily worse he was sent to the hospital. The diagnosis of rupture of an abdominal viscus was based on the marked abdominal tenderness and the boardlike rigidity of the abdominal muscles and free fluid in the abdominal cavity, but there were no localizing symptoms. The abdomen was opened in the middle line above the umbilicus; a large quantity of fluid and clotted blood escaped on opening the peritoneum. The liver was found normal, but on passing the hand into the splenic region a large quantity of clot was displaced and free bleeding was found to be going on. A large rupture in the spleen was felt. When the splenic vessels were grasped, the bleeding stopped. The splenic vessels were isolated and ligatured with linen thread and the spleen was removed. The wound was sutured with linen thread. The spleen was normal in size and weight; the tear, which extended from the convex surface to the hilum, divided the organ into two equal portions. There was no stripping of the capsule to suggest that at first there had been subcapsular hemorrhage, later tearing through the capsule. It was clear that the tear in the spleen and capsule were present from the first, allowing of free intra-abdominal hemorrhage. Microscopic examination showed the spleen to be normal. The patient recovered. Four weeks after the operation he was apparently in the best of health.

Relation of Pfeiffer's Bacillus to Influenza.—No agglutination of either one of three typical strains of Pfeiffer's bacillus was obtained by Wyard with serums removed from fifty-nine cases of influenza, whether those cases were or were not complicated by bronchopneumonia, and whether they

were in the first, second, third, fourth or fifth week of the disease. Attempts were made to discover antibodies by means of complement fixation tests, but in no case was the complement fixed.

*Treatment of Recurrent Malaria. H. Fraser.—p. 1134.

*Congenital Dislocation of Hip: Method of Dealing with Refractory Cases. A. H. Tubby.—p. 1135.

Hysterical Sleeping Attacks.—Carlill reports the case of a young man, aged 19 years, who, since early childhood, had been liable to go off to sleep at any time and without any feeling of fatigue. He had never been a week free from this. Except for enlargement of one of the turbinate bones, examination revealed no evidence of organic disease in any system. The boy's physical health was good. He was not addicted to bad habits. The Wassermann reaction was negative both in serum and in cerebrospinal fluid, and the fluid was in all other respects also perfectly normal. Carlill was confident that the attacks were hysterical, due to his own suggestion; in other words, the patient hypnotized himself. His head was roentgenographed and he was told that the real cause of his illness had been discovered, and that an operation for the removal of a piece of thickened bone was necessary in order to effect a complete and permanent cure. Carlill trephined the skull in the right parietal region and removed the disk of bone. The dura mater was healthy and was left alone. The bone was normal. Directly the patient regained consciousness, he was shown the piece of bone and given it to feel, and he was told how successful the operation had been. From the date of the operation his sleeping attacks ceased entirely and he admitted that he was absolutely cured. He did not relapse. The patient has remained perfectly well since his operation eighteen months ago.

Occasional Manifestation of Malaria.—Twenty cases are reported by Jones to demonstrate that malaria has a place, though a small one, among the hemorrhagic diseases. Instances are given of bleeding from the mucous membranes of the alimentary, respiratory and urinary tracts, into a solid organ like the spleen, and into the eye. Two cases of arthritis were observed in this series, one with effusion into a knee joint. Jones insists that hemorrhage of any kind occurring in a malarial subject should be regarded as an indication for treatment with quinin. Malarial subjects should be advised to take a calomel purge followed by quinin by the mouth immediately on feeling the slightest headache or malaise; by this method it appears that recurrences can frequently be averted. To assist clinical diagnosis of the infection, the presence of areas of hyperalgesia over the distribution of the eighth cervical and first dorsal, the seventh dorsal and the lumbar segments, or some of these, may be taken as a good rough indication that the patient is suffering from malaria, provided that trench fever infection can be excluded.

Treatment of Recurrent Malaria.—Fraser claims that no man can have a relapse of malaria during the period that he swallows 15 grains of quinin sulphate in solution once daily. Smaller doses are not sufficient, and it is better to give the amount in one dose rather than in divided doses. Fifteen grains of quinin taken daily can do no harm to any man infected with malaria parasites. If a relapse occurs, the man is either not swallowing or not absorbing the quinin. It has not been determined how long the continuation of treatment is necessary. It was not found practicable to

continue the treatment beyond twenty-eight days in hospitals or concentration camps for malaria. It is advisable to continue the treatment for as long as possible. In the absence of treatment or in cases inadequately treated relapses are observed. In these cases, 15 grains of quinin sulphate in solution should be given twice daily for five days and thereafter 15 grains once daily. The first dose should be given when the temperature is falling—that is, in the sweating stage. No patient suffering from a relapse without complications, who is treated in this way, will show a rise of temperature subsequent to the fourth day. No importance is attached by Fraser to the use of tonics, such as iron and arsenic.

Congenital Dislocation of Hip.—Tubby claims that in congenital dislocation of the hip the ilio-psoas muscles and tendons undergo important changes in direction. As the combined muscle tendon crosses the brim of the pelvis, it is displaced outward and it passes closely beneath the anterior inferior spine. It then winds outward and backward to its insertion, compressing the capsule about its middle, and this is responsible for the hour-glass shape of that structure, so often seen in cases of congenital dislocation in children more than 4 years of age. As age advances, the ilio-psoas muscle and tendon become more hypertrophied and thick; they compress the capsule of the hip-joint more closely about its middle, and the latter becomes not only hour-glass shaped, but its anterior wall is so folded inward and backward as to obscure the entrance to the acetabulum like a curtain. This constriction of the middle of the capsule is by no means an insuperable obstacle to reduction in early life. As time passes, however, the narrowing or hour-glass contraction of the capsule increases. By continuous narrowing, the aperture leading from the outer portion of the distended capsule into the true acetabular cavity may be reduced to a small button-hole. The cavity is thus obliterated, its site being covered over by the outspread attachments of the anterior layer of the capsular ligament. In these cases Tubby makes a crucial incision of the capsule and divides the constriction of the capsule and the ilio-psoas tendon. With a little traction on the limb, the caput femoris slips easily into its socket. The crucial incision into the capsule is then closed by suture, and the limb is put up in plaster in the fully abducted position. The result has been entirely successful. Tubby has been able to advance the age for operative reduction of the hip from 7 years onward, until the latest successful case occurred in a girl, aged 15 years.

Suppurating Hydatid Cyst of Liver. R. L. Ley.—p. 1195.

Primary Hydatid Disease of Brain.—Fleming and Bury make a detailed report of a case of this kind occurring in a soldier. A diagnosis of cerebral tumor was made. As the operation was about to commence, breathing ceased, but the pulse and all reflexes remaining normal, artificial respiration was resorted to, and a left subtemporal decompression was performed. The patient did not take a normal breath for four and one-half hours and without the administration of any anesthetic whatsoever. The condition of increased intracranial pressure had existed for a considerable time before the operation, and the anesthetic had further increased the pressure and so paralyzed the respiratory center beyond recovery. The patient died. At the necropsy, on slicing the left cerebral hemisphere, a unilocular cyst, equal in size to a large orange, escaped from the ventricle. The cyst had apparently no attachments to anything in the ventricle; the appearance of the cyst was typical of a hydatid. The cyst

was found to have bulged into and greatly distended the left ventricle, causing pressure on the surrounding parts, particularly the internal capsule, lenticular nucleus, and optic thalamus. It is the authors' opinion that the parasite had come via the choroid plexus. On dissecting the right hemisphere three calcified nodules one-sixth of an inch in diameter were found embedded in the middle frontal convolution. Nothing else abnormal could be found in the brain. The fluid in the cyst and the fluid obtained from aspirations of the left ventricle were found to contain hooklets and scolices, proving it to be due to *Tenia echinococcus*. The calcified nodules were examined, and a report of "amorphous calcified material" was returned. In spite of this, however, the authors submit that they were calcified nodules of *Tenia cysticercus*.

Boiled Vegetables for Diabetics.—Very little experimental work appears to have been done on the composition of the material resulting from the treatment of vegetables with three changes of boiling water. It has been generally assumed that any vegetable of low carbohydrate value is rendered practically carbohydrate-free, while vegetables of high carbohydrate content, and particularly root vegetables, should not be used. With a view to throwing some light on the question and discovering which are the best vegetables to employ for the purpose, a number of experiments were carried out by Cammidge. From these experiments it is clear that three boilings are not sufficient to render all vegetables carbohydrate-free, and that the amount of carbohydrate originally present is no guide in selecting those best suited for the preparation of a starch and sugar-free product such as may sometimes prove useful instead of actual fasting for children or persons who have severe cases of diabetes. It would seem that celery, rhubarb, spinach, sliced turnip and sliced carrot can probably be relied on and are the best to use for the purpose. Even when thrice boiled vegetables are not quite free from carbohydrate, the percentage is so much reduced that from four to thirty times as much of the thrice boiled as of the once boiled material will contain the same amount of carbohydrate.

Aspiration of Tuberculous Abscess.—Given an early diagnosis, Fernandez claims that treatment by aspiration will frequently arrest the course of a tuberculous abscess and effect a complete cure. Delay in diagnosis and treatment by incision not infrequently end in disaster.

Carcinoma of Ovary.—In the case cited by Gerson, an exploratory laparotomy had been performed, a provisional diagnosis of tuberculous peritonitis having been made. The right ovary and tube were found involved in a growth and were removed; no secondaries were observed at the time. Within a few weeks after operation a lump was noticed in the left iliac region, and on the presumption that the left ovary was involved, a second laparotomy was performed, which revealed a malignant growth of the left ovary and multiple secondaries in the omentum. The case was considered inoperable. The patient died two weeks later. Microscopically, a large papillary carcinoma, tubular and cystic, consisting of polygonal and cubical cells, was found in the left ovarian mass. Secondary carcinoma were found in the vagina and external os, the submucosa of the bladder, and the subserosa of the great omentum. A noteworthy fact was that no secondaries were found in the kidney on the right side, from which the corresponding ovary had been removed at the first operation.

*Infant Mortality. W. F. Litchfield.—p. 479.

Food Factor in Gastro-Intestinal Diseases. R. D. Luker.—p. 481

Digestive Disorders of Artificially Fed Infants.—That every baby is a law unto himself in capacity, digestive power and assimilative process is a point emphasized by Harrison. Psychic and material individuality are as characteristic of infancy as of adult life. General guiding principles are essential, but no rigid hard and fast rules can be laid down to fit every case, for the baby is a living entity and not a machine with standardized parts. One must study, examine and handle each baby personally if success is to be attained.

Infant Mortality.—From a study of the infant mortality statistics of Australia and New South Wales, Litchfield concludes that during recent years there has been some agency in operation that has reduced very considerably infant mortalities. This has been widespread and uniform in its manifestation. Its influence has extended to the second, third and fourth years of life, and it has operated by diminishing the number of deaths from infective processes, especially those affecting the bowels and lungs in young children. It has been independent of public health measures and welfare schemes and there has been no great change in the habits of the people during the period of its occurrence. The only thing Litchfield can attribute it to is a widespread but obscure climatic effect.

*Gases of Warfare. H. Fredericq.—p. 105.

*Sarcoma of the Stomach. H. Koettlitz.—p. 136.

Diaphragmatic Hernia; Two Cases. A. Colard.—p. 144.

*Clinical Examination in Diseases of the Nervous System. M. Molhant.—p. 149; Idem. R. Marchal.—p. 222.

Gases in Warfare.—Fredericq says that now that the censorship is a thing of the past, he is free to write a general review of this subject based on personal observation and experiences and those of others, as well as on the strictly censored literature. He remarks that the use of gases is not a new thing in warfare. "The Inquisition in striving to influence the heretics of Dauphiné used the gases from the combustion of green wood as a means of collective asphyxiation. In 1845 General Pellissier resorted to the same means in reducing the rebellious Arabs in Algeria, but he was denounced for this in the French legislature. The Japanese also used toxic gases, produced in a more scientific manner, in their campaign against the Russians in 1905." Fredericq says further that German documents which fell into the hands of the Allies showed that shifting of the wind, sweeping the gas back on them, did great damage to the Germans themselves in May, 1915, and on other occasions. The Germans did not have the advantage of the world weather reports, as the Allies' newspapers did not publish meteorologic reports during the war.

Sarcoma of the Stomach.—Koettlitz reports a case of gastric sarcoma with chylous ascites and involvement of the pancreas. He compares this case with the few on record; Gosset's compilation in 1912 included only 171. As metastasis is rare and as the sarcomas are often pedunculated, operative treatment offers considerable chances for a cure. His patient refused intervention for forty-five days after the tumor and achylia had been diagnosed, and the growth then was inoperable.

Disease of the Nervous System.—From the standpoint of the general practitioner, Molhant gives the pathogenic interpretation and diagnostic value of the clinical signs with disease of the nervous system. The clinical exploration in these cases differs so fundamentally from other clinical cases

that the physician often feels at a loss. This first installment of his article is accompanied with thirty-three illustrations.

Marchal expatiates on the importance of an early diagnosis in these cases, so that the patient can be referred to a specialist in time for treatment to be effectual. He says that it does not take more than two minutes to test the pupil, tendon and skin reflexes and automatism when a patient complains of more or less vague pains and tendency to paresis of a member.

*Resection for Gastric Ulcer. J. Abadie.—p. 370.

*Treatment of Hemophilia. P. Emile-Weil.—p. 374.

Measurement of Speed of the Heart Impulse.—Lapique announces from his further study of chronaximetry that in the normal heart the functional velocity of the bundle of His is always in a given ratio to the functional velocities of the different cavities of the heart. The variations from this ratio offer a new mode of research on the heart in pathologic conditions, and to study the effects of drugs.

Malta Fever from Cheese.—The cheese made from goats' milk was the only possible source that could be discovered in the case of undulant fever in western France.

Gastrectomy for Ulcer.—Abadie declares that all the arguments against gastrectomy in opposition to palliative operations fall flat now that experience is confirming the comparative harmlessness of gastrectomy. It puts an end definitely and permanently to all disturbances from the stomach and menace of malignant disease later. There is no other field of surgery that is more useful from the practical standpoint as, other things being equal, it transforms a long suffering invalid into a normal, vigorous producer.

Serum Treatment of Hemophilia.—Emile-Weil reported in 1907 a very severe case of hemophilia since early childhood in a man of 26, much improved by injection of human or animal blood serum. These injections were kept up afterward for five years, 20 c.c. of serum every two months, and there have been no hemophilic hemorrhages since, the blood coagulating in a nearly normal manner. Six other patients have been treated by the same continuous method, and five have been freed from recurring hemarthroses, hematuria, etc., but the blood in none is quite normal. In the sixth patient the improvement was less and there have been some recurring hematomas. There never were any serious anaphylactic phenomena in any of the cases, but slight symptoms were sometimes apparent; in one not until after the sixteenth injection, and then none again. Others had them after the first injection and not afterward, slight joint trouble or urticaria, with fever, never anything serious.

Nervous Symptoms from Retroparotid Space. F. Bonnet-Roy.—p. 807.

Adjuvant Medication in Syphilis.—Balzer urges the necessity for treating superposed infections, and fighting to ward off sclerosis, and to arrest incipient tabes and parietic dementia. Serotherapy might aid in overcoming the barriers which sclerosis interposes to protect the persisting foci of spirochetes. Attempts to strengthen the organism and reinforce the defences are also in order. Measures to stimulate leukocyte production, and organotherapy might be considered. Measures that have been found useful in the chronic pathologic conditions entailed by syphilis might prove far more effectual if used early, before these conditions had become so firmly entrenched. He thinks this adjuvant medication has been neglected too much to date.

Bulletin de la Société Médicale des Hôpitaux, Paris

*Tuberculin Reaction in the Pregnant. Nobécourt and Paraf.—p. 1013.
Missing Niphoïd Appendix in Inherited Syphilis. Queyrat.—p. 1015.

Diagnosis of Tracheobronchial Glandular Disease.—Méry refers to some recent clinical experiences in which the radiologic and the necropsy findings were absolutely superposable. This comparing of the clinical and radiologic findings is one of the most instructive modes of research.

True Herpes Zoster.—By this term Sicard means the form that confers immunity and never recurs. He says that the aspect of the skin after the eruption has healed is characteristic, as definite and permanent minute scars are left on the patch of skin affected. This does not occur with the zosteriform type of herpes. This latter form is often the prelude to irritation of a spinal root from compression. Hence herpes zoster in adults should be regarded with suspicion until it has established its identity by the scars left.

Syphilis and Tuberculosis.—This communication from South America emphasizes the unsuspected frequency of inherited syphilis as a predisposing factor in the status lymphaticus, in asthenia and in more or less complex endocrine derangement. Even when no signs of inherited syphilis can be detected, tentative specific treatment is justified, and it may transform conditions previously refractory to all treatment. This is particularly indicated when the parents are robust and free from alcoholism, tuberculosis, malaria and lead poisoning, which might explain the degeneracy of their children. Tuberculosis so often develops on a basis of syphilis, that inherited syphilis should be suspected, particularly in the masked cases. Tentative specific treatment in addition to the usual treatment for the tuberculosis may induce such improvement that the organism then can throw off the tuberculosis.

The Blood Pressure.—Villaret and Dufour apply the Pachon oscillometer cuff to the upper arm, the Laubry sphygmophone to the bend of the elbow as usual, and palpate the radial pulse, all at the same time. They thus combine the oscillometer, auscultation and palpation methods, each acting as a control of the others, and the findings are recorded on a single chart. They describe a simple method for calculating a constant to express the coefficient of the different findings. It has confirmed the modifications in the normal blood pressure during digestion and in the erect position.

Loss of Immunity During Pregnancy.—Nobécourt and Paraf applied the tuberculin skin test weekly to 100 women during the last half of pregnancy and after delivery. This showed that pregnancy and parturition may induce an inability to react to the tuberculin test—a tuberculin anergy like that noted in certain infectious diseases, especially measles. This reduction in the sensitiveness to tuberculin usually corresponds to a parallel reduction in the immunity. This state of anergy—especially pronounced after childbirth—may explain the aggravation in tuberculous processes which is so apt to follow delivery.

*Ossification in the Eye. L. Bussy.—p. 368.

*Old Cartilage Graft in Skull. A. Policard and J. Murard.—p. 378.

Sequels of Sprains of the Knee.—In this general review Tavernier discusses the various indications with the different sequels of a sprain of the knee. For dislocation of a meniscus, he opens the joint transversely, and sutures the lateral ligament with the knee half flexed, and immobilizes, and has had invariably good results, the patients able to run and jump. But there is a sideward movement when the knee is half flexed, not in other positions. Some do not notice it at all; those who do notice it may complain that the knee is weak. He shows that all the consequences of a sprain of the knee can now be effectually combated with some of the new or older operations. They have proved their harmlessness and efficacy in correcting the serious infirmity liable to be entailed by a sprain.

Ossification in the Eye.—Bussy discusses the mechanism of the bone formation sometimes observed in an atrophied eye or stump of an eye.

Fate of Cartilage Implant in the Skull.—At necropsy thirty months afterward, the cartilage implant was found fastened to the skull around with connective tissue, but there was no direct union between cartilage and bone. This fibrous soldering answered the purpose here, but it might not be strong enough to stand much movement of the parts. The perichondrium seems to protect the cartilage graft against being resorbed. In this case there had been very little resorption.

*Depth in Radiology of the Heart. Vaquez and Bordet.—p. 465.

*Arsphenamin Jaundice. E. Chabrol and A. Khoury.—p. 467.

*Vitamins and Growth. Houlbert.—p. 473.

Seven Cases of Typhoid in One Family; No Water Contamination. Apert and Cambassès.—p. 476.

The Depth Index in Radiology of the Heart.—Vaquez and Bordet report from study of 1,000 cases that when the depth index is normal, while the diameters of the heart are exaggerated, the right cavities are pathologically enlarged, as a rule. When the reverse occurs, that is, the index is exaggerated while the diameters are normal, the left ventricle is often pathologically enlarged in the depths. Or else the heart is displaced, which is easily determined. The depth index is the difference between the profile of the apex as marked on the screen directly and then again after the tube has been moved 10 cm. to the left. With a distance of 60 cm. from the focus to the screen; the normal difference between the two profiles, the subject standing, is from 7 to 14 mm. The expansion of the chest does not modify the findings. The findings with this index always corresponded to the clinical findings in the case.

Arsphenamin Jaundice.—Chabrol and Khoury present an array of clinical data and emphasize the importance of a predisposition on the part of the liver as a factor in the toxic jaundice from arsphenamin. Several of their cases show the extra vulnerability of the liver from a pregnancy, tendency to gallstones, and hereditary cholemia. Antecedents of this kind call for special caution in administering a drug with a reputation for inducing jaundice. One of the longest and best known types of hemolytic jaundice is that induced by arseniuretted hydrogen. How else except by toxic action can we explain the jaundice which develops in 20-year old

syphilis after a course of ten or twelve injections of arsphenamin?

Vitamins and Growth.—Houlbert has been studying the action of vitamins on the division and multiplication of cells. Two of three chickens of the same hatching were fed on polished rice, wheat and barley, all sterilized, and twice a week a little cod liver oil was given them to ward off polyneuritis. Cell division was found completely arrested in the sexual and hematopoietic glands examined in one chicken at the fortieth day. The other was then kept on the same diet, but a few drops of a vitamin were added to the feed, and the chicken began to thrive at once. When killed the thirty-second day it was evident that the endocrine glands had pursued their normal evolution after the primary arrest of the forty days of the deficiency diet.

*Prophylaxis of Tuberculosis. A. Calmette.—p. 773.

*Spirochetal Bronchitis. Najih Farah.—p. 774.

Prophylaxis of Tuberculosis.—Calmette insists on the importance of some of the more recent acquisitions in our knowledge of tuberculosis, such as that the tuberculous with occult or latent lesions may suddenly begin to eliminate tubercle bacilli in their glandular excretions or their dejecta. This intermittent elimination by these occult carriers is very common, but is seldom recognized. He reiterates further that no person and no animal contracts tuberculosis, no matter how unhygienic the environment, unless virulent tubercle bacilli have been brought into this environment by some human or animal continuous or intermittent spreader of these bacteria. All our efforts therefore should be predominantly directed to ward off this importation of the bacilli, especially frequent importations and on an extensive scale. Every one who reacts to the tuberculin test—even though apparently entirely healthy—is an intermittent spreader of germs, the more dangerous because unsuspected. They are the ones who disseminate contagion even in the remotest regions of the world. It will always be difficult to discover these intermittent sowers of bacilli, either human or bovine. But every person or animal reacting positively to the tuberculin test should be regarded with suspicion, and young children and young domestic animals in localities still free from infection should be guarded against them, and against contamination of milk and food, by hands, towels, flies and street and other dust. The reservoirs of virus in open tuberculous cases in man and animals are the source of the massive and frequent contaminations which entail phthisis even in adults. To guard their environment against them requires insight and science on the part of physicians and veterinarians, and training in hygiene for all interested, either because they have to live with the sick or fear loss of their herd.

Spirochete Bronchitis.—Farah reports gratifying results in ten cases of Castellani's spirochetosis in which intramuscular injections were given of iodine in an oil vehicle. There has been no relapse in any of the cases since May, 1918. From five to ten daily injections were given, followed by another series at two or three days' interval. By the fifth injection there were scarcely any spirochetes to be found. One of the patients had had the spirochetosis for eight years. No other member of the family had contracted the disease in any instance, confirming the slight contagiousness. The same treatment apparently proved equally effectual in his two cases of monilia bronchitis.

Revue de Chirurgie, Paris

May-June, 1919, 38, No. 5-6

*Toxicity of Crushed Muscle. P. Delbet and others.—p. 309.

*Varicocele. O. Jacob.—p. 352.

*Sporotrichosis from Surgical Standpoint. P. Moure.—p. 366.

Toxicity of Crushed Muscle Tissue.—Delbet and his four co-workers injected 213 normal animals with crushed tissues, macerated and filtered, taken from 121 other animals. This extensive research on 114 rats, sixteen dogs, sixty-eight guinea-pigs, thirteen frogs, one cat and one rabbit has con-

firmed the assumption that crushed and devitalized tissues generate the toxins which bring on shock. In war wounds and in peace crushing injuries the main thing is to clear out all the devitalized tissues before they get the chance to poison the whole system. Some of the animals displayed remarkable resistance to the injections while others succumbed at once. Those that succumbed, he noticed, were the carnivorous animals while the herbivorous guinea-pigs and rabbits were the most resistant. He accepts this as a hint to drop meat from the diet but otherwise feed patients abundantly before and after operations, mostly with vegetables. Soldiers who had been eating much meat seemed to develop traumatic shock more readily than others, while those from rural districts, accustomed to a more vegetarian diet, seemed more resistant to traumatic shock.

Operative Treatment of Varicocele.—Jacob has had no recurrence in the 237 cases of varicocele in which he resected from 6 to 8 or 15 cm. of the anterior spermatic veins, close to the inguinal canal. The peripheral stumps were then tied together and drawn up by the ends of the ligature into the superficial inguinal ring where they were fastened to the pillars of the ring.

Surgical Importance of Sporotrichosis.—Moure emphasizes that sporotrichosis does not require surgical treatment, but that its localizations and clinical symptoms are liable to deceptively simulate other pathologic conditions for which operative measures would be imperative. He declares that the textbooks on pathology should devote some space to this mycosis as well as to syphilis and tuberculosis, to avert blunders from its nonrecognition. It should be looked for in all subacute and chronic suppurations, to prevent needless and often harmful operations. If not convenient to make cultures or test for agglutination, nothing is easier than to give a tentative course of iodid treatment. Under this, sometimes, old suppurations which have resisted all surgical interventions may melt away as if by magic. He advises testing the tolerance, as about 10 per cent. of patients are more or less intolerant of iodids. He gives a daily dose of 2 gm., gradually increasing to 4, 6, 8 and 10 gm. The useful dose is from 4 to 6 gm., and potassium iodid, sodium iodid and iron iodid might be associated, adding the syrup of bitter orange peel, and supervising the antiseptics of the bowel. The dose should be fractioned and taken with meals, and the treatment kept up for at least a month after the apparently complete cure of all the lesions. If surgical measures are required for osteitis with sequestrs, it is better to defer them till after the iodid has been taken for some time.

Revue Médicale de la Suisse Romande, Geneva

October, 1919, 39, No. 10

Influenza in 1918. C. Krafft.—p. 465.

*Simplified Serologic Test. J. Golay.—p. 493.

Simplified Serologic Test.—Golay's technic differs from Noguchi's in a number of minor points which, he says, increase its precision while materially simplifying the technic, as he describes. In 150 persons tested, the reaction was positive in 100 per cent. of the syphilitics and was negative in 100 per cent. of the nonsyphilitics.

*Effect of Occlusion of Pancreatic Duct. E. Bernucci.—p. 996.

Nov. 20, 1919, 40, No. 93

Poisonous Mushrooms. G. Ferri.—p. 1013.

Effect on Peristalsis of Occlusion of Pancreatic Duct.—Bernucci gives twelve sets of radiograms showing the progress of the food in stomach and bowel after the pancreatic duct had been ligated or had become obstructed from other cause. The experiments were made on dogs. The effect was most marked on the progress of fat foods, less marked with protein foods, and scarcely any effect was seen on carbohydrates. These effects are analogous to those from ligation of the common bile duct, but they are not so pronounced as with the latter. With obstruction of the pancreatic duct, the stomach is the segment of the digestive tract that feels the retarding effect most.

Red Cross Welfare Work for the Tuberculous. C. Baduel.—p. 1395.

*Treatment of Purulent Pleurisy. E. Pittarelli.—p. 1396.

Vitamins in Urine.—Gaglio writes from the Pharmacology Institute of the University of Rome to confirm his previous announcements (May 25, 1919) that pigeons with pronounced polyneuritis from being fed with polished rice recovered from the otherwise fatal polyneuritis when they were treated with human urine, two or three times a day in doses of 3 or 4 c.c. of the urine, slightly condensed in the water bath. "The effect was more decisive," he adds, "than Funk realized with extract of rice hulls, which resulted in his assumption of the hypothetical vitamins."

Aspiration of Pus from the Pleura.—Pittarelli gives an illustrated description of his aspirator which, automatically and simultaneously presses and aspirates, so that the pressure inside the pleura is not modified in the least, the whole proceeding independently of the intrathoracic pressure. The double-ended syringe has a tube and needle at each end. The two plungers are worked simultaneously by a thumb-screw in the center. One thus aspirates while the other forces in air or fluid. A disinfecting fluid can thus be sent through the pleura until it comes away clear. The only inconvenience is the necessity for introducing the two needles.

*To Reveal Latent Malaria. A. Dazzi.—p. 1413; Idem. T. Silvestri.—p. 1418.

*Serous Traumatic Peritonitis. G. Aboularage.—p. 1427.

Metal Stand for Needle for Intravenous Injection. A. Cerioli.—p. 1429.

Means to Reveal Latent Malaria.—Dazzi reports trials of various means that have been proposed to induce a malarial paroxysm in suspects, and states that a subcutaneous injection of 1 mg. of suprarenal extract best answers the purpose. No quinin was allowed for five days before, and the blood was examined before, twenty and sixty minutes afterward, and the next day. It does not induce a malarial attack, but it drives out the parasites into the blood at once and up to an hour, but by the next day none may be found. The epinephrin induces also a marked reduction in the size of the spleen, commencing at once and continuing for several hours.

Silvestri prefers strychnin for the purpose; from 1 to 3 mg. by the mouth daily. The simplicity and efficacy of this provocative measure commend it, he declares, the febrile attack developing not later than the third or fourth day.

Traumatic Serous Peritonitis.—The circumscribed peritonitis followed a contusion and the abdomen had to be tapped several times, the child dying of cachexia in a month, although the viscera seemed normal.

Rivista Critica di Clinica Medica, Florence

Oct. 18, 1919, 20, No. 42

*Progress in Organic Nervous Disease. F. Schupfer.—p. 493. Conc'n.

Recent Progress in Organic Disease of Central Nervous System.—Schupfer states that no light has been thrown on the pathology of the frontal lobes nor on aphasia, apraxia and epilepsy by the war experiences, but the war wounds of the cerebellum have confirmed the latest acquisitions of science, especially in regard to centers in the cerebellum

controlling the action of both the acting and the antagonist muscles. It was learned further that wounds of the spine were not so grave in the cervical region as lower down. If eschars, infection of the bladder and pleuropulmonary complications can be warded off, there may even be notable improvement. The difference in the gravity of the lesion as it is high or low is explained by the wider space for the cord in the spinal canal in the cervical region.

- *Malta Fever in Children. J. Aguilar Jordán.—p. 577.
- *Calcium Balance in Children. C. S. de Los Terreros.—p. 595.
- Scrap of Bone in Rhinopharynx. A. Martin Calderin.—p. 606.

Malta Fever in Children.—Aguilar Jordán reiterates that no drugs have proved effectual in treatment of Malta fever. Vaccines and antiserums seem to offer promise of better results, although in his own experience they have proved disappointing. He has been quite successful with antityphoid autovaccine therapy in children, since 1913, and thinks that improved technic will aid in vaccine treatment of Malta fever. The experiences with it in Italy lately by Caronia and others have been most satisfactory, as duly reported in these columns.

Calcium Balance in Children.—De los Terreros explains that calcium and its compounds have a much wider sphere of action in children than has been suspected till recently, not only in rachitis and tuberculosis, but in spasmophilia, epilepsy, true hypotrophy, neoplasms, etc. The loss of calcium balance is comparatively common in children. It should be suspected in any one of the above conditions, and be investigated by analysis of the urine and stools, study of endocrine disturbances, the blood count, chemical analysis of the blood, and radiography of the bones.

- *Cholesterol as Factor in Immunity and in Production of Agglutinins. T. Morató and G. Villanueva.—p. 137. Conc'n.
- *Treatment of Spindle-Cell Osteosarcoma. C. Calderón.—p. 139.
- Useful and Harmful Coughs. G. Triviño.—p. 140.

Cholesterol and Immunity.—Morató and Villanueva found that cholesterol mixed with typhoid vaccine and injected into eighteen rabbits seemed to hasten and enhance the production both of antibodies and of agglutinins. The addition of the cholesterol also seemed to reduce the general reaction to the antityphoid vaccine. They also cite further some recent research by others testifying to the benefit from administration of cholesterol in toxi-infections in which the cholesterol content of the blood is below the normal figure. Among others mentioned is Iscovesco's favorable experiences in tuberculosis, Revillet's in exophthalmic goiter, and Monziol and Castel's in malaria. The latter declare that cholesterol tends to render the cells more susceptible to the action of quinin.

Treatment of Sarcoma.—Calderón advised disarticulation of the hip joint in the case of a youth with a spindle-cell osteosarcoma on the leg. The parents refused to consent to such a mutilating operation for "merely a little bunch on the leg," and they asked to have the bunch cut out and the bone scraped. He refused to do this, confident that it would merely whip up the malignant disease. The parents found another surgeon more complaisant, but the curetting hastened the course and death speedily followed. He urges others to resign a case rather than do such unscientific and injurious operations as curetting in these circumstances.

There are fifty-seven pages of fine plates accompanying the article on the entameba and the report of the scientific mission to study the mosquitoes and pathology of the Paraná district.

Experimental Influenza.—The experiments on monkeys, guinea-pigs and other animals at the institute confirmed that the filtered virus was able to induce influenza in animals. The intense and prolonged rise in temperature after the inoculation is accepted as the criterion of the reaction to inoculation of the animals with blood and filtered sputum from influenza patients. The period of incubation, the immunity conferred by the first inoculation, and the absence of any reaction when the filtrate had been heated or treated with phenol, testified that the hyperthermia was the work of a living agent and not a toxic fever. Virulent filtrates heated and phenolized seemed to display a curative action. Autohemotherapy is often effectual, which testifies further to the presence of the virus in the blood, as also the precipitation reaction between the sputum filtrate and convalescents' serum. There is no fixation reaction between human serum and the filtrate of the influenza sputum.

- *The Factors in Hydromineral Treatment. Rodríguez Pinilla.—p. 90.
- *Influence of Uranium on the Blood. F. Más Magro.—p. 110.

The Nucleins in Pathogenesis of Gout and Diabetes.—Fernández presents arguments in favor of the assumption that both arthritism and diabetes are the result of defective metabolism of nucleins or of their immediate derivatives.

Thyroid Deficiency.—Collar gives the history of two children with congenital myxedema, the photographs showing the great improvement realized under a year of thyroid treatment begun at the ages of 4 and 11. The thyroid extract was taken regularly two or four times a day. The treatment was not begun till 18 in another case in which the symptoms of thyroid insufficiency had developed at the age of 10. Under fifteen months of thyroid treatment the girl grew taller, and the breasts and genital organs developed; menstruation became regular and free from headache. Among the symptoms were albuminuria and tendency to somnolency and chilliness, and she never perspired even during the summer. Slight or partial insufficiency of the thyroid is hard to differentiate, as it appears under so many different aspects, especially a tendency to obesity, to transient edema not located by gravity, appearing in the arms, hands and legs and in the lower lids, especially in the morning. The voice also may be weak, from infiltration of the

vocal cords. The tendency to somnolency and to chilliness is also a prominent symptom, and there are often vasomotor disturbances, numbness in the fingers, etc. The hairs in the outer half of the eyebrow may drop out, and there is usually constipation and headache in connection with menstruation, and neuralgia is common. There is very little perspiring, except possibly in the hands; the sweat here contrasts with the cold clamminess.

Fistulas Into the Kidney.—Serés has operated in three cases for renal fistulas in the lumbar region, and describes the etiology, complications, and preferable operative technic for such lesions from suppuration or calculi in the kidney. Functional tests of the kidney showing normal conditions demonstrate an extrarenal origin for the fistula; they are indispensable in any event as they reveal whether the kidney is worth saving or not.

Crenotherapy.—This classic term for treatment by water from mineral springs deserves more general adoption, although the term "spa treatment" includes much more than the waters. The repose, change of scene and diet are important adjuvant factors, Rodríguez emphasizes. He adds that crenotherapy cannot be classed as physiotherapy, like sunlight, heat, electricity and exercise. Although the waters are a natural agent given by Nature, yet their action is physicochemical, not physical alone, and each spring is an individual, a living thing, as is evident by the loss in its potency when carried away from its source. The mineral water acts more like a ferment; comparatively small amounts accomplish great transformation, while physical agents act proportionately to their quantity.

Influence of Uranium on the Blood.—Más Magro reports the results of extensive experimental research on the action of uranium on the blood-producing organs. A subcutaneous or intraperitoneal injection of a 2 per cent. solution of uranium acetate in rabbits and guinea-pigs caused an epithelial nephritis with death the sixth or seventh day. This is the effect of the minimal lethal dose. When death occurs in three hours and a half, the blood shows coagulation, thrombosis, precipitation and agglutination. Uranium thus does not induce death directly.

- *Operations for Pulmonary Tuberculosis. L. Morales.—p. 97. Conc'n.
- *Chemical Analysis of the Blood. F. Poyales.—p. 108. Conc'n.
- *Nutritional Derangement and Rachitis. P. Pereda y Elordi.—p. 117.
- Periphrical Facial Diplegia from Influenza. W. López Albo.—p. 141.

Operative Treatment of Pulmonary Tuberculosis.—Morales concludes from his review of the various surgical measures that have been applied in pulmonary tuberculosis, that there is every reason to call in the surgeon where the disease is progressing in spite of well-planned and systematic medical treatment. No attempt should be made to resect the lung itself or open a cavity, as these interventions are extremely grave under these circumstances and the result doubtful; at most, a very large cavity might be opened up under very special circumstances. Procedures to ensure the collapse of the lung favor the natural healing processes, and among them paravertebral thoracoplastics gives fine clinical results, but phrenicotomy, he affirms, is the simplest measure and has good effects to its credit. It is indispensable, he reiterates, that the disease must be confined to one lung. He describes the technic for phrenicotomy, saying that it is harmless, never causing disturbance in the respiration or heart functioning nor dyspnea. Under local anesthesia, through an incision 10 cm. long at the outer margin of the sternocleidomuscle, the phrenic nerve is exposed and severed.

Practical Analysis of the Blood.—Poyales describes various simplified procedures for chemical analysis of the blood, all within the reach of the general practitioner. His numerous references are all to American works.

Nutritional Disturbances and Rachitis.—Pereda's profusely illustrated account of his experience with debility and rachitis in children teaches anew that the osteoporosis which follows deprival of calcium in the food is not rachitis,

and never runs into rachitis, so long as there is not chronic intoxication of digestive origin. When this autointoxication is corrected, then conditions right themselves, if this occurs in time to ward off irreparable lesions. The whole cause of true rachitis he traces to defective digestion of fats, aided perhaps by a relative congenital intolerance. Treatment should not include calcium, as there is enough in ordinary food for the infant's requirements.

- *Shock after Delivery. N. Buendia.—p. 57.
- *Case of Pseudohermaphroditism. Martín Méndez S.—p. 68.
- Criminal Responsibility of the Insane. A. Gaitán U.—p. 72. Conc'n.

Shock After Delivery.—Buendia refers to a set of symptoms after abortion and normal delivery which seem to form a state of shock, although the loss of blood was not excessive and no operative measures had been attempted. It seems to be more frequent in tropical than in temperate climes, and in women who have borne a number of children; those inclined to neuropathies are predominantly affected. He describes six cases of this "essential postpartum shock," with its profound depression of the circulation and respiration, and partial or total loss of consciousness and sensibility. Hypodermic injection of epinephrin proves so effectual that it throws light on the etiology.

Pseudohermaphroditism.—Méndez gives an illustrated description of another instance of blunder in sex, the androgynoid being unmistakably of male sex, although baptized and brought up as a girl.

Revista Médica de Chile, Santiago

November, 1919, 47, No. 11

- *Anomalies in Bile Ducts. J. Alvarado.—p. 813.
- Syphilitic Disease of Orbit and Skull. C. Charlin C.—p. 816. Cont'n.

- Vagotomy in Syphilis. Prado Tagle and C. Garcés.—p. 860.
- *Typhus. A. Atria.—p. 867. Conc'n.

Anomalies in Course of Bile Ducts.—Alvarado describes two cases in which the cystic duct lay behind the hepatic and parallel to it, and emptied into it from the rear.

Congenital Luxation of Hip Joint.—Díaz reviews the present status of treatment of this condition in Chile and especially in the children's hospital at Santiago, studying in particular the causes of failures. Perseverance and patience are needed here more than anywhere else, he remarks, quoting in conclusion Amunátegui's saying that orthopedics is the most ungrateful of specialties, as it takes so extremely long to get results.

Puzzling Ovarian Cyst.—Lachaise diagnosed an extra-uterine pregnancy from the fluctuating tumor reaching above the umbilicus and not changing its position, while he could palpate the fetal head. Laparotomy showed a large ovarian cyst, fastened by adhesions, and a myoma which had been mistaken for the fetal head. There was no sign of pregnancy.

Treatment of Ectropion.—Martini had always been disappointed with the results of plastic operations on the eyelids until he applied the Italian method of a pedunculated flap. In a case reported the woman never complained of disturbances in the arm, while the outcome was highly satisfactory.

Typhus Fever.—Atria is chief of the bacteriology section of the Public Health Service, and he closes his report on the recent typhus epidemic by reiterating that the diagnosis of typhus must be based on the clinical picture, the negative findings with tests for typhoid, and the character of the epidemic. The Nicolle biologic reaction is useful only in experimental research and not for the clinical diagnosis.

- *Edema of Larynx as Complication. D. Hernando Seguí.—p. 495.

Edema of Larynx as Complication.—Seguí discusses the possible primary causes of edema of the larynx, from syphi-

lis, drinking scalding fluids, trauma, such as a kick in the neck in football, kidney disease, neurotic edema or laryngeal urticaria, and iodid edema. The latter is more common than generally recognized, and is liable to cause fatal asphyxia if potassium iodid is given when the lumen of the larynx is already somewhat obstructed by pathologic infiltration. He warns expressly against iodid when there is the least tendency to edema. Whatever the cause, treatment should be with absolute repose, opium and bromid to quiet the cough, very cold or very hot applications around the neck, and spraying the larynx with a suprarenal-cocain solution, preparing for the tracheotomy which may become necessary. He advises the intercrico-thyroid operation as easy, rapid and harmless; only in case of chronic disease, with secondary edema, the tracheotomy had better be lower. Angioneurotic edema calls for rapid derivative measures and disinfection of the bowel; edema with chronic nephritis indicates a purge, theobromin, and suppression of salt in the food.

*Cough from Reflex from the Ear. G. M. Landa.—p. 528.
Sterilization According to the Pharmacopœia. H. González Arrieta.—p. 530.

Reflex Cough from Impacted Cerumen.—Landa was unable to find any cause for the spasmodic cough in the young child except signs of eczema and excess of wax in one ear. There was no further coughing after the ear had been cleared out. The cough resembled whooping-cough, but it occurred only during the daytime. The nerve connection readily explains the irritation of the external laryngeal nerve from pressure by cerumen on nerve fibers in the ear.

*The National Tuberculosis Sanatorium. E. R. Coni.—p. 421.
Diluted Vaccine Therapy of Typhoid. P. H. DeDomenici.—p. 433.

Complications of Otitis.—González emphasizes the necessity for referring a patient with otorrhea to a specialist without wasting time on ordinary measures, relating a case in which the practitioner tried various measures for over two weeks before sending the patient to the ear surgeon. By that time the cerebral abscess had reached an inoperable stage. Sixteen illustrations are given of the necropsy findings in the brain. The anatomic specimens in this case, the brain, meninges and temporal bone, form an object lesson on the danger of delay in cases of otorrhea. The set is to be kept together in the museum, so that it can be studied in preparing monographs on pathologic conditions in this region.

The National Sanatorium at Cordoba.—Coni took charge of this sanatorium in June, and this is his formal detailed report of its condition and of his work there during his less than three months' incumbency. His resignation accompanies the report; the deficiencies and disorganization discouraged him too much to continue his work there.

*Transformation of Sanatoriums into Villages. J. Sixto.—p. 1004.
Diagnostic Tests for Syphilis. D. T. Morató Cárdenas.—p. 1005.

Serotherapy of Anthrax.—Murillo comments on the "extraordinary frequency of anthrax in Spain, and the fact that it is so seldom fatal, notwithstanding the gravity of the lesion." He estimates that there must be from 2,000 to 3,000 cases in Spain every year. It has been given as the cause of death in from 0.56 to 1.09 per thousand of the total deaths since 1904. Several hundreds of patients have been treated with an antiserum, made at the Instituto de Alfonso XIII, with very favorable results. Sheep and horse antiserum have given the best results to date, except the experiences with normal beef serum recently reported from Argentina with a death rate of only 1.5 per cent. in the first series of 200 cases and of 11.6 per cent. in a later 172 cases. The average thus was 4.5 per cent.

Village for the Tuberculous.—Sixto urges that a model village be planned for the tuberculous instead of a merely hospital or sanatorium existence. Each family would have its own house, some member of the family serving as the attendant of the tuberculous. He calculates that the expense would be about a third more per bed than in the sanatorium, but the advantages would outweigh this. The tuberculous would take advantage of treatment at an earlier stage if they did not have to be separated from their family.

The Biology of Lymphocytes.—As the result of his experiments on guinea-pigs and rabbits, Bergel has reached, in regard to the classification of lymphocytes, certain conclusions that are at variance with the doctrines of Ehrlich. The investigations of Ehrlich brought him to the conclusion that the polymorphonuclear, neutrophil leukocytes and the mononuclear, basophil lymphocytes were, by reason of their different morphology, genesis and staining characteristics, to be regarded as distinct cell types. Bergel had shown previously that the lymphocytes contain a fat-splitting ferment. This finding strengthened Ehrlich's conception of two distinct cell types, as it gave proof of a functional difference. The knowledge of the presence of the ferment made it easier to understand biologically and clinically the lymphocytosis regularly observed in many conditions; for example, it explained the increase in the lymphocyte count brought about by a diet rich in fat, and also the part the lymph nodes play in the assimilation of fats. On the other hand, Bergel finds that the lymphocytes should be viewed more comprehensively than Ehrlich viewed them; that is, Bergel would classify functionally as lymphocytes the mononuclear cells and also the transitional forms that are characterized by a crescent-shaped (but never polymorphous) nucleus and by a non-granular basophil protoplasm, for the reason that such cells may develop from or into typical lymphocytes. Bergel claims to have shown that also the small lymphocytes have ameboid motility and phagocytic power for fats. He thinks he has proved by means of oil and lipid injections that these substances exert an elective chemotactic influence on the lymphocytes within the vessels and attract vastly more mononuclear lymphocytes than polymorphonuclear leukocytes. The lymphocytes thus migrate out of the vessels, seize the fat globules with ameboid protoplasmic processes, and digest them or pass them on to the lymph nodes and the spleen.

*Influence of Ovaries on Glycemia. C. Baillo.—p. 1897.
*Blood-Platelet Extract by the Mouth. W. Jost.—p. 1909.

Influence of Ovaries on Sugar Content of Blood.—Baillo concludes from his clinical and experimental research that whereas injection of epinephrin in physiologic conditions raises the sugar content of the blood to a certain extent, this reaction is more intense and occurs more rapidly in the absence of ovarian functioning.

Action of Blood-Platelet Extract by the Mouth.—Jost reports that the blood platelet extract known as coagulen is absorbed by the digestive tract. Given by the mouth, it aids materially in shortening coagulation time. It thus helps to combat a tendency to hemorrhage, but in urgent cases the subcutaneous and intravenous routes should be used at the same time.

Access to Projectile in Front of Second Cervical Vertebra. Remmets.—p. 111.
*U Clamps for Fractures. Remmets.—p. 118.
*Isolated Fracture of Acetabulum. Kreglinger.—p. 129.

Pathogenesis of Steeple-Skull.—Rieping gives an illustrated description of an infant born with extreme oxycephaly. The details of twenty-one particularly pronounced cases of steeple-skull from the records are tabulated, and the possibility of various methods of operative intervention is discussed. His case confirms that oxycephaly is the result of a displacement of the primary ossification center of the frontal and parietal bones toward the coronary suture. This entails the premature growing together of the latter. It may be inherited, with other malformations.

Clamps for Fracture.—Remmets' clamps are shaped like a very broad U, the pointed tips triangular to ensure a perfect hold. The ends of the bone are held in place with forceps like veterinarians' hoof-tongs, the handle resting on the table, and the clamp is driven in with a holder and hammer. The limb can be moved cautiously from the very first, and only a light dressing is required. The staple can be applied through a small incision in the skin. He has used these staples in twenty-seven cases, some of which are illustrated to show the fine results realized.

Fracture of the Acetabulum.—Kreglinger's experiences testify that with early diagnosis and proper treatment the outlook is favorable for permanent healing without special deformity.

Composition of the Blood in Arid Climates.—At the congress of German internists, held in 1911, the supposed beneficial effect of arid climates on renal and respiratory diseases was discussed. The supporters of the view that a dry climate is beneficial based their belief on the assumption that in arid climates the increased secretion by the sweat glands and the kidneys brought about an increased excretion of waste material. For this reason, they argued, an accumulation of urinary constituents in the blood—enough to induce uremia—could not take place. This made it desirable to study the blood in arid climates. Grober was chosen for a three months' study of the question, and on the advice of expert geographers southern Tunis in northern Africa was selected for his investigations. Belad el Djerid, or the date palm country, the latitude of which is 34 north, was the exact spot chosen. To the south lies the Sahara Desert; to the north, extensive salt marshes, dry in summer. The mean winter temperature is 12 C. (53.6 F.) the summer temperature ranges usually between 30 and 40 C. (86 and 104 F.), the maximal temperature being, however, above 50 C. (122 F.). The minimal temperature is slightly below freezing. It hardly ever rains, and even cloudy days are rare. Rain is often absorbed by the dry atmosphere before it reaches

the earth. Through government aid (the country is a French protectorate), religious and superstitious scruples were overcome and 200 subjects were secured. Many were rejected because of intestinal parasites, malaria and syphilis. The records of only seventy-nine of the healthiest subjects were taken. The primitive inhabitants, the Berbers, and Arabians were selected in preference to others, as they had been exposed longest to the climatic conditions. No peculiar difference in form or staining characteristics of the red and white blood corpuscles were noted. Blood specimens had to be from finger pricks, other means being prohibited on religious grounds. The average results of the blood tests were: erythrocytes, 6,300,000; hemoglobin, 99; specific gravity: whole blood, 1.057, blood serum, 1.026; refractometric determination of albumin, 8.5; solids, 22.24 per cent. The red cell count was much higher than among Europeans. Hemoglobin was also slightly increased. The rest of the values are not significant. Grober therefore reaches the conclusion, which he regards as important from chemical, pathologic and physiologic standpoints, that even under extraordinarily low humidity conditions, such as were found in Tunis, the blood preserves its usual composition. The assumption that in arid climates there is an increased excretion from the blood of urinary constituents by way of the sweat glands is therefore refuted. This does away then, he thinks, with the supposed indications for sending kidney patients to arid climates.

The Significance of Devitalized Tissue in Gas Gangrene.—Weil found that a small fraction of the ordinary lethal dose suffices to cause the death of guinea-pigs when the causative agent of gas gangrene is introduced into crushed or torn muscle tissue, whereas in healthy tissue the growth of the causative agent is checked at once. This proves that healthy tissue has a marked defense reaction that is lacking in damaged tissue. The conclusion would therefore seem justifiable that a slight gas gangrene infection in a crushed or lacerated war wound would develop rapidly and practically unhampered. The spread of the infection does not depend alone on the number of gas bacilli but also on their virulence, or ability to form toxins. The virulence of the bacillus may be an inherent quality of a given strain before entering a wound, or the high virulence may be developed within a wound, owing to the presence of torn tissue. The pathologic-anatomic picture of the infection produced by the Fraenkel strain was practically the same in animals whether the causative agent was introduced in torn or in healthy tissue. It was found that the bacillus of malignant edema could cause edema and also be a gas producer, which verifies clinical experience. Weil's experiments, furthermore, proved conclusively that gas gangrene serums have slight or no protective value if the seat of the gas infection is in devitalized tissue, and that serotherapy must be supplemented by surgical measures if gas gangrene is to be avoided or combated.

Clinical Importance of the Colloidal Gold Reaction.—The main difficulty with the colloidal gold reaction, Eicke finds, is the preparation of the colloidal gold. The trouble lies in the extreme sensitiveness of colloidal gold to chemical influences; even the alkalinity of the glass may give the solution a bluish tinge and render it useless from the start. Another frequent cause of failure is that fresh, doubly distilled water is not used. The colloidal gold reaction furnishes an interesting proof of the baneful effect of exceedingly slight impurities in water. The main value of the colloidal gold reaction is that it gives us a means for the early diagnosis of neurosyphilis. At the Rudolf Virchow Hospital, Berlin, it has established the syphilitic origin in many obscure cases. In one case of optic neuritis, the etiology was baffling. The personal and family history was negative. The blood Wassermann test was negative, but the colloidal gold reaction gave the typical curve of cerebrospinal syphilis. The patient, who was seriously ill, was at once given specific treatment with good results. If it should prove possible to simplify the preparation of the colloidal gold, this reaction might be regarded as ideal and would be of the greatest value to medicine.

 *Old Irreducible Hernias. L. Schönbauer.—p. 1093.

Pathology of the Peripheral Arteries in Acute and Chronic Cardiac Insufficiency.—Wiesel has long asserted that many of the clinical symptoms which are commonly ascribed to failure of the heart muscle, or traced to nervous, vasomotor influences, have in reality their origin in pathologic changes in the peripheral or outer arteries. The clinical symptoms in impaired circulation frequently could not be explained by postmortem anatomic findings. Often in serious cases the heart was found practically unimpaired. On the other hand, postmortems of elderly persons had revealed that chronic disturbances of circulation do not always accompany atrophic hearts. Wiesel and Löwy admit that anatomic findings alone do not suffice to give an absolutely clear picture of the causes of disturbed circulatory function, but they think their findings in twenty cases that came to necropsy may form a basis for further research. Arteries from various parts of the organism were examined histologically, and the findings showed pathologic conditions in at least all the chronic cases of impaired circulation. The degree to which the circulation was impaired also corresponded in a general way to the various stages in the disease of the arteries. The disease affects primarily the middle coat and spreads later to the elastic coat, the intima being rarely invaded. This is the main feature differentiating the disease from arteriosclerosis; nor were atheromatous patches found in the media, such as are found in the intima in atherosclerosis. The process that Wiesel and Löwy describe is purely degenerative and not inflammatory. The starting point may possibly be the vasa vasorum, of which they found some indications. Recovery is not excluded, but they regard the changes within the vessel walls as ordinarily permanent. They characterize the various stages of the degenerative process as follows: (1) foci of edematous infiltration in the tunica media; (2) separation of the muscular fibers so that they present a ragged appearance; (3) along with changes in the nuclei, muscular degeneration, evidently the result of faulty nutrition; (4) formation of necrotic foci; (5) restorative processes: muscle formation, atypical fiber layers, long muscular fibers in annular muscle; (6) evidences of cicatrization and calcareous infiltration in the tunica media.

Irreducible Hernias of Long Standing.—Schönbauer says that the main difficulty and the chief danger that is encountered in any attempt to reduce by a radical operation a large hernia of long standing is that during the course of time the abdominal space has become much retracted, so that there is no longer room for the intestine. If by dint of much work the hernia is reduced, serious abdominal distention is likely to follow, which will frequently result in the diaphragm being pushed upward, possibly to the third rib. This condition may have fatal consequences. If reduction of the hernia is extremely difficult, he thinks it is better to resect a portion of the intestine, up to three meters. If this is not done and incarceration results, it may be necessary to remove an even greater portion. He describes two fatal cases; the hernias were of twelve and thirty years' standing. Death occurred from crowding of the lungs in one case, plus incipient peritonitis in the other.

 *Pituitary Diabetes. J. Koopman.—p. 1071.
 *Case of Gastric Syphilis. W. F. Suermondt.—p. 1076.

Postoperative Raying.—Van der Haer relates that there has been recurrence in only one of his twenty cases of mammary cancer in which the site of the cancer was exposed to the roentgen rays after its removal. In twelve the interval

since has been three years and in all it has been over two years.

Organotherapy in Diabetes.—Among the arguments in favor of the assumption that more than one endocrine organ may be involved in the production of diabetes, Koopman mentions that the suprarenals have sometimes been found diseased in diabetes; that the reaction to phlorizin is often exceptionally severe in exophthalmic goiter, suggesting involvement of the thyroid; that this excessive reaction is not observed after partial thyroidectomy, and that the tolerance for carbohydrates is abnormally low with exophthalmic goiter. Müller has reported a case of the latter given thyroid treatment; sugar appeared then in the urine and the patient died in diabetic coma. Such facts suggest some participation of the thyroid in the etiology of diabetes. The pituitary also may be involved. Diabetes has been observed in 40 per cent. of the cases of acromegaly, but acidosis and coma are extremely rare in such cases. Steiger could find only five cases in his compilation in 1917. In one of Stadelmann's two cases, after death in coma, the pituitary was found diseased but the pancreas was apparently sound. In Steensma's case, the girl had diabetes and a tendency to obesity; radiography showed abnormal conditions in the sella turcica; carbohydrates could not be tolerated, but pituitary treatment gave good results.

Koopman has encountered two cases of pituitary diabetes which he describes in detail, calling attention to the absolute intolerance of albumin in both. The first patient, a man of 40, had no glycosuria after 100 gm. of bread, but after 50 gm. bread and 50 gm. meat there were 38.6 gm. sugar, and after 100 gm. bread and 50 gm. meat, 69.2 gm. sugar. The roentgen findings in the pituitary region were normal and the Wassermann reaction negative. But after three days of tentative pituitary treatment, no sugar appeared in the urine after ingestion of 200 gm. bread and 50 gm. meat, and even when this meat ration was doubled, only 16.4 gm. sugar was found in the urine. The patient during a whole year presented glycosuria whenever the meat ration was increased, while carbohydrates did not increase the sugar content. Whenever the pituitary treatment was interrupted, sugar appeared in the urine by the second day. Acetone and diacetic acid were never observed after the very first. The second patient presented much the same picture, but radiography was not available. The glycosuria was brought under control with pituitary treatment but the man wearied of it in two months and of the restriction of meat, and dropped the whole, dying three months later in coma. In conclusion Koopman extols the Allen fasting treatment of diabetes as probably destined to be "the" treatment, and points out that a trial of this may aid in the differentiation of this pituitary form of diabetes. In any event, the trial can do no harm. The classic method of estimating the tolerance does not give an insight into the metabolism in diabetes; the sugar content of the blood is more instructive than that of the urine. If a special susceptibility to albumin is discovered, the pituitary should be thought of.

Syphilis of the Stomach.—In Suermondt's case there was nothing to suggest syphilis in the woman of 47 who had had stomach symptoms for seven years, ascribed to ulcer: local pain, worse at night, and occasional vomiting, but no blood in vomit or stools. After a few mouthfuls she always felt as if the stomach was full. The roentgen findings were interpreted as plastic linitis, but the operation revealed syphilitic changes in the small contracted stomach and in the liver. Under specific treatment the outline of the stomach grew larger and there was no further vomiting. Six roentgenograms taken at intervals during the six months show the characteristic findings before and after treatment.

RELATION OF THE DEVELOPMENT OF THE GASTRO-INTESTINAL TRACT TO ABDOMINAL SURGERY*

W. J. MAYO, M.D.
ROCHESTER, MINN.

THE RELATION OF ANATOMY TO PRESENT DAY SURGERY

The late Corydon L. Ford, professor of anatomy at the University of Michigan Medical School, was justly considered the greatest teacher of anatomy of his time. I well remember the three years in which I studied anatomy under him, and the impression he made on the students by his clear and forceful presentation of this ordinarily dry subject. He was then a man past middle life; he wore a beard, shaved the upper lip, and because of a congenital clubfoot he walked with a decided limp by the aid of an ivory-headed cane. I speak of these physical factors because they were part and parcel of the man in relation to his teaching. He presented anatomy not alone as a fundamental science which it was necessary to master for the purpose of laying a foundation for clinical medicine, but as a living thing to be considered in almost every professional act. He was closely in touch with the clinical issues of his time, and with anatomy he taught most valuable lessons in physiology and pathology, so that the student gained knowledge of his subject in its relation to his work. The university courses in surgical anatomy were excellent, yet Ford taught us more surgical anatomy than we learned in these special courses, and he also taught us medical anatomy, in order that we might see the patient from the anatomic standpoint, and recognize pathologic deviations from the normal in the early stages. We were drilled in the use of Holden's "Anatomical Landmarks"; I have spent many hours with this little book, going over the living body that I might learn the relation of the external to the internal.

As volunteer assistant I had the further privilege of demonstrating anatomy at the University of Michigan, and the fascination for anatomic detail in relation to medicine and surgery has remained with me. My seat companion was the late Franklin P. Mall, afterward professor of anatomy at Johns Hopkins, and the most distinguished anatomist of his time. Mall was a choice spirit, an anatomist of the research type. On one occasion in showing me the manner in which the heart, by

its peculiar twisting contraction, empties all the blood from its cavities as one would wring a cloth, he remarked that a cavity like the bladder cannot empty itself to the last drop by contractions alone. He said that anatomy since Ford's time had dealt too much with abstract matter. Mall's observation has an important bearing on catheter cystitis, an infection of a small amount of residual urine in an overstretched organ.

During my active experience in surgery, working with many different assistants, I have not always been impressed with their knowledge of anatomy, although all have possessed a fair knowledge of pathology. At times it would seem that they were more familiar with minute pathology than with anatomy. Microscopic histology and pathology, while not overdone, have been allowed to overshadow anatomy and gross pathology—these the surgeon or internist must see with his own eyes if he is to do his best work. It is a question in my mind whether, generally speaking, anatomy is as well taught today as it was in my student days; whether it is taught with a view of instilling in a man a love for the subject, or merely as a foundation for medical practice. I believe this tendency is correctly interpreted by teaching anatomists of the type of Jackson and others, who are taking steps to remedy the existing defects by the better balancing of anatomic teaching. This is also true of the teaching of present day pathologists.

In surgery of the abdomen especially, a wide knowledge of embryology and anatomy is essential. In the olden time when operations were done in late periods of pathologic conditions, and were destructive rather than reconstructive because it was necessary to save life and it was too late to save function, one could fully appreciate the answer of the distinguished surgeon who originated excision of the hip when asked concerning the anatomic details of the operation: "Damn the anatomy; stick close to the bone." Today the bulk of surgery is not done for gross defects but for pathologic conditions which have not deviated from the normal to such an extent that destructive surgery is necessary, but are still in condition for reconstruction. It has been said that the anatomist never made a good surgeon; that it was the pathologist who made the surgeon. This is true only of the vanishing German type. The surgeon of tomorrow must follow in the footsteps of such men as Deaver; he must be an anatomist and a physiologist, and living pathology must hold a greater place in his mind than the pathology which has been developed from the mortuary and has dominated medicine for the past generation.

For many years I have been interested in elucidating problems of surgery of the abdomen. Clinical diag-

* Mayo Foundation lecture, given before the University of Minnesota Graduate School of Medicine and the Physicians and Surgeons Club, Rochester, Minn., Dec. 4, 1919.

nosis has been notoriously unreliable, and the postmortem does not show the chronic disease from which the patient was sick during life, but rather the particular complication from which he died. Always, when I have faced a new problem in this field, I have gone back to embryology, anatomy and physiology in order to gain an idea of the meanings of those pathologic deviations which we are called on to treat. It may not be out of place at this time to outline sketchily some of the anatomic and physiologic principles that have grown up with the surgery of the abdomen, and on which depends the explanation of many phenomena that could not otherwise be understood.

From the time the food passes through the pharynx until it enters the rectum we have comparatively little control over it. Some control is exercised in the esophagus and even in the fundus of the stomach so that by initiating retrograde movements, retching, and so forth, some food may be ejected. The same is true in the sigmoid; but even in it the control at best is but partial and indirect. The biologists have pointed out that the theory of the three blastodermic membranes is a working rule and not a law, having many exceptions; but at least it leads to logical thought. To a certain extent this is also true of the idea of the derivation of the gastro-intestinal tract from the fore, middle and hind guts. Yet these primitive derivatives, while not as exact in the present day human body as might be desirable from a purely scientific point of view, have great value as outlines for the student.

From the foregut come the stomach, the duodenum down to the common duct, the liver and the pancreas, all organs which prepare food for digestion but do not themselves absorb. The stomach does not absorb even water, although it will take up certain chemicals and poisons, alcohol, for instance. The derivatives of the hindgut likewise absorb nothing except certain chemical substances, and rectal feeding, as spoken of in its ordinary sense, does not exist: it is simply a means whereby material placed in the rectum is quickly carried by what Bond calls "mucous currents" back into the derivatives of the midgut for absorption. The so-called colon tube passes out of sight through the anus, coiling in the rectum, and but seldom passes the rectosigmoid barrier. The derivatives of the foregut have their blood supply from the celiac axis. The derivatives of the midgut, in which absorption takes place, are supplied from the superior mesenteric artery, while the inferior mesenteric artery supplies the derivatives of the hindgut as far down as the rectum, and very largely the rectum also, although the rectum and anal canal obtain a small supply from the middle and external hemorrhoidals because of their origin from the cloaca and the proctodeum.

Rosenow's work on the specificity of bacteria shows that bacteria that have been cultivated in certain soils, in the gallbladder, for example, when placed in the circulation, are peculiarly attracted to the organ to which they have been acclimated. That is, strains of bacteria derived experimentally from a gallbladder will more often set up a cholecystitis than if they were derived from some other organ. This is true along so many lines connected with the vascular system that we must admit at least the possibility that the blood supply is to a certain extent specific and that organs exercise some peculiar chemotaxis which physiologically and pathologically directs certain substances of the blood content to them. How else can we explain the rapidity with which phenolsulphonephthalein is

eliminated through the kidneys? And recent work in physics suggests that the attraction may be a physico-chemical one. Very delicate instruments appear to show that each organ has its own electrical reactions and polarity, suggesting that cancerous growths can be recognized in this way.

Embryologically the first portion of the duodenum ends, not at the pylorus but at the common duct, and the duodenum above the common duct embryologically is a part of the stomach and a vestibule to the small intestine; like the stomach and other acid-containing organs, it is extremely liable to ulceration. Ulcers of the duodenum occur more commonly in men than in women, possibly because the first portion of the duodenum in women is more nearly horizontal, naturally permitting of a higher alkaline level for the bile and pancreatic juice, and thereby reducing the liability to ulceration. In animals with bilocular stomachs the division between the two stomachs is at the incisura of the human stomach, and the physiologic activity of the pyloric half of the stomach, especially at the incisura, is quite evident on roentgen-ray examination, although the musculature composing the primitive sphincter has disappeared.

The termination of the absorbing intestinal area in the transverse colon near the splenic flexure embryologically marks the end of the absorbing area. It is interesting to note that, although the proximal half of the large intestine has no marked anatomic differences from the left half, in the embryo villi are to be found in the right half which are similar to the villi of the small intestine, although they disappear as development proceeds. An observer, watching with the roentgen ray the churning back and forth in the head of the colon sees that the greater part of this activity is proximal to the location of the cecocolic sphincter which exists in the ascending colon of some of the lower animals, and that physiologic contractions are most marked in this situation. Retardation of the passage of food through the intestinal tract has its origin in embryologic physiology. Muscular control by means of sphincters, delay by means of the valvulae conniventes which also present larger exposed surfaces for absorption, delay by sacculations, as in the large intestine, and mechanical delays, such as the high attachments of the splenic flexure which necessitate muscular activity in order to pass the food refuse into the nonabsorbing part of the large intestine and render the descending colon physiologically empty, are examples. The rectosigmoid is a most remarkable mechanical device for retardation of food end-products. Since nature is most sparing of waste, even of water, in the terminal half of the large intestine, especially the sigmoid, the fluids are gradually squeezed out of the refuse and passed by reverse currents back into the proximal half of the colon for absorption.

Rotation has great surgical significance. In the embryo and in many lower animals throughout life the stomach hangs with its lesser curvature facing ventrally; and embryologically the lesser curvature is the anterior wall of the stomach. Rotation turns the stomach and pancreas on their right sides. The pancreas, embryologically an intraperitoneal organ, loses its posterior layer of peritoneum, which becomes fused behind with the fascia. This explains why, in the type of acute pancreatitis and fat necrosis which might be picturesquely called "perforation," the pancreas may involve the fat behind the peritoneum as well as the intra-abdominal fat; why occasionally, in traumatism,

pancreatic secretions escaping into the lesser cavity of the peritoneum may penetrate into the omentum and form a collection of fluid in what is known as the omental bursa, reopening the cavity which in fetal life exists between the layers of the omentum before they are fused as high as the transverse colon.

The position of the duodenum is altered by rotation and its third portion becomes retroperitoneal, a fact of great importance in connection with operations on the right kidney. Unless care is exercised in performing a nephrectomy in cases in which there is chronic inflammation around the pelvis, and especially in malignant disease, the duodenum may be injured, and immediately or a few days later a fistula form from which the patient may die unless it is repaired anteriorly by a transperitoneal operation. Very scanty mention of this accident is found in the literature, but I have reported several cases of this character. Unless careful dissection is made, this retroperitoneal portion of the duodenum also may be injured in the removal of cancers of the ascending colon.

Rotation as it affects the intestinal tract is also of great surgical importance. The large intestine, having its origin on the left side of the body, passes to the right and does not reach its normal situation until after birth. The late peritoneal attachments are often described as veils or adhesions, and are given unwarranted credit for causing trouble. Failure of rotation or partial rotation will cause the physical signs of an appendicitis to appear at whatever point the rotation of the head of the colon is interrupted. The attachments of the large intestine to the right side are not only late and less close than those on the left, but also, since the cubic capacity of the right lower thorax is less than that of the left lower thorax, because of the liver, the right kidney normally lies lower than the left. The nephrocolic ligament may be called on to bear much of the weight of the head of the imperfectly attached colon which acts like the car attached to a balloon, and may, by traction, drag the kidney down. We think of the large intestine as having a short mesentery; but as a matter of fact, it has a very long mesentery on the inner side, which is the only side of importance, as the blood vessels, lymphatics and nerve supply are always to be found in the inner long leaf which follows the colon during its migration. The outer peritoneal attachments which hold the colon in place laterally may, therefore, be divided without encountering any structures of importance, and the large intestine, on its long inner leaf of mesentery, can be drawn out of the body for easy manipulation and operation. There is one exception, that is, the attachments of the splenic flexure are derived from the omentum and contain a blood vessel which must be tied. Some years ago I called attention to this method of mobilizing the large intestine, which is based on these anatomic facts and very greatly aids in operations on the colon.

The small intestine, originating in six primary convolutions on the right side, has its mesenteric attachment from left to right, from above downward, passing behind the umbilicus. This is the reason why in obstructive and other disturbances of the small intestine, unless localized by involvement of the peritoneum, the pain is referred to the vicinity of the umbilicus, although the cause of the pain may be in a loop of intestine at a distance. In picking up a loop of small intestine, it is sometimes difficult to determine which direction is up and which is down. Monks, in a beauti-

ful piece of work, has shown how this can be done with facility. If a loop of intestine drawn out of an abdominal incision is held by an assistant, and the surgeon, grasping the intestine with the fingers on one side and with the thumb on the other, passes down to the bottom of the mesentery, and finds that his fingers and thumb still grasp the root of the mesentery as started above, the direction is up and down; but if the position is reversed at the base, then the direction is the opposite. In picking up a piece of small intestine one should be able to recognize the part of the bowel from its appearance. The upper jejunum is thick and wide, the mesentery is thin, and the vessels are large, long and straight, having but one or two primary arcades close to the base. In the lower ileum the intestine is thin and the mesentery thick, the fat sometimes following the vessels a little way up along the intestinal wall. The vessels are smaller, shorter, and there are a number of arcades, sometimes two, three or four, in the adjacent mesentery. Attention to these details makes ready differentiation possible.

The study of the peritoneum is profitable to the surgeon. The resistance of the peritoneum to infection is an inherited faculty. The meninges and pleura have less resistance. In the earthworm (common angleworm), the food, in its progress through the primitive gastro-intestinal canal, is admitted into the coelom, or body cavity, which is the forerunner of the peritoneum, for direct absorption. The contaminated peritoneum before infection takes place usually needs no drainage after mechanical cleansing; drainage often does harm rather than good. The slowly acquired special resistance of the pelvic peritoneum of women to infections in the course of countless generations of suffering from puerperal and other infections, is well known; and the mortality rate of operations involving the pelvic peritoneum, such as resections of the rectum for cancer, is much less in women than in men.

Let me repeat that the teaching of anatomy, as related to constructive surgery rather than to the destructive surgery of the past, should be based on the needs of the surgeon of today, to enable him to cope with the diseases of today. If I were to write a book (I have no intention of inflicting one on the medical public), I should take up the fascinating story of embryology, anatomy and physiology in relation to the work of the surgeon of tomorrow, the story of the anatomy of the living to enable us to treat the pathology of the living during the early stage of deviation from the normal physiologic state.

COORDINATION OF THE FUNCTIONS OF THE GASTRO-INTESTINAL TRACT

The two most primitive functions of a living body are maintenance of nutrition, and reproduction; and nature has thrown about these functions the greatest possible number of safeguards. First, the body must be nourished, and second, new life is to be brought into being. This is as true of the simple cell as of the most complex organism. The more ancient the organ, the greater its resistance. The small intestine has an enormous resistance to disease and seldom is the seat of neoplasm. The testicle, which is the primitive reproductive organ, has a long heredity and freedom from disease. On the contrary, the ovary, which is descended from the testicle is, like other less ancient organs, such as the stomach, the rectum and the large intestine, a frequent seat of neoplasm.

Methods of control over the visceral functions were established before man had a central nervous system; these controls are still independent of it. It might even be surmised that the attempt of the central nervous system to gain control over visceral and other functions previously established may have to do with neurasthenia, especially its visceral manifestations. Starling well says that those internal secretions which he calls hormones precede all types of nervous systems in visceral control. One is perhaps justified in looking on the sympathetic as the more primitive nervous system and in believing that the means whereby the central nervous system is attempting to gain this control over the vegetative functions is through the autonomic nervous system.

The liver, entirely separated from all its connections, can be made to secrete bile, and the kidney similarly to secrete urine. For that matter, the entire viscera have been completely separated experimentally from the nervous system and even lifted out of the body, and by appropriate mechanical connections made to live and function for some hours. The central nervous system, we find, has more or less control of those organs which have been added more recently, especially organs of convenience, such as the fundus of the stomach, into which a quantity of food may be placed rapidly for elaboration, as the magazine of a coal stove may be filled. The sigmoid and the bladder also have temporary storage function; but in other respects the central nervous system, beyond initiating action, plays a small part in vegetative life.

The growth of the central nervous system in relation to the organs of special sense is interesting. First, the sense of taste, which made the selection of food possible; second, the sense of smell, which enabled the primitive stoma to be turned toward food, and third, the sense of hearing, which was placed in the middle of the head because danger threatens from behind as well as in front. The sense of sight came during the rapid development of all the higher cerebral faculties, and direct pathways were established between the eye and all parts of the brain, so that the sense of sight overshadows in importance the other special senses. Even memory in most persons has its basis in visual phenomena. The relatively short heredity of the central nervous system accounts for its instability.

It is interesting to note that the sympathetic nervous system is in close relation with the endocrine glands, and that the importance of the internal secretion of an organ may be estimated by the closeness of its relation to the sympathetic system. The pituitary, one-half sympathetic and one-half gland, the suprarenal, with its similar association, and the thyroid, are examples; the spleen has no internal secretion of great importance, and only small connection with the sympathetic system.

Still another form of control is found in the primitive character of the nonstriated muscle. These fibers have the power of originating motion independent of a known nervous system. A little piece of the wall of the small intestine will contract for hours when placed in Locke's solution and properly stimulated. Many visceral functions are dependent on the nonstriated muscle. We are indebted to Keith for revelations with regard to the curious nodal system which acts to collect the impulses that have their origin in the primitive fibers of the nonstriated muscle. This has been most carefully studied with reference to the heart. The heart-beat starts in the sinu-auricular node, is

diffused through the auricular musculature, and is passed by the muscle-band of His to the ventricles, timing the ventricular beat. Keith's nodes are composed of a curious type of primitive muscle-cell with some fine fibers from the autonomic nervous system which evidently were added later. These nodes are in effect the controlling ganglions of the action of the nonstriated muscle in organs. Keith has pointed out the situation of eight nodes, four located and four not fully identified, through which control is maintained. When food passes through the pharynx, all direct control is at once lost, and here is situated the first node: The cardia is a true sphincter and normally is closed. The food passing through the esophagus arouses contractions in the nonstriated muscle of the esophagus; these impulses are carried to the second node, which relaxes the cardiac orifice. Failure to relax the cardiac orifice results in that curious condition called cardio-spasm from which many persons suffer and starve for years, and often die from obstruction supposed to be due to cancer. If we have knowledge of the nature of the disease, cure is easy and certain. The third node is not at the pylorus as one would think, but at the termination of the primitive foregut near the common duct. It is interesting to note that, as pointed out by Ochsner, there are remnants of a prehistoric sphincter at this point. Disturbances of this node produce the condition called pylorospasm, which accounts for many gastric disturbances masquerading under different names. This node is also concerned in chronic gastric atony and some of the phases of acute dilatation of the stomach. The fourth node is near the duodenojejunal juncture and is concerned normally in peristalsis and in segmentation or pendulum movements of the small intestine, and abnormally in producing gastromesenteric ileus. The fifth node is at the ileocecal juncture and is concerned with many of those phenomena about which Lane has written so interestingly under the general head of ileac stasis. The sixth node is near the middle of the transverse colon, and through its control of antiperistalsis prolongs the retention of food products for absorption in the right half of the colon. The seventh node is in the rectosigmoid region, and disturbances in the function of this node are probably responsible for the giant colon of Hirschsprung's disease. The last, or eighth, node is concerned with rectal control.

It may be said that wherever nonstriated muscle exists, the power of originating contraction exists. The intestine, like the heart, has two beats. The first, called the peristalsis, beats once or twice to the minute. The second, as pointed out by Mall, is the heart of the portal circulation and beats from eighteen to twenty times a minute, forcing the blood to the liver. In the pregnant uterus, the beat of the nonstriated muscle is recognized as the uterine contractions of pregnancy. Keith points out the part played by the nodes in controlling peristalsis, and suggests that they act like a block system on a railroad, and control food progress by controlling sphincters.

The endocrine glands secrete substances which Starling has called hormones; they act through the blood stream and form a most interesting chapter in visceral control; they are closely allied to the sympathetic nervous system, and are often found in glands of double function or glands that at one time have had an external as well as an internal secretion. The gonadal

- secretion derived from the interstitial cells of the generative organs controls sex characteristic even when the genital elements are absent. The relation of the external pancreatic secretion dealing with the digestion of fats, starches and proteins has only an indirect connection with the tissue of Langerhans, which has to do with sugar metabolism. The thyroid in the king scorpion is a reproductive gland, and the thyroid function in the human being is closely connected with puberty, in the female, with the pregnant state. Types of life are found in which the thyroid functioned through the digestive tract, and the foramen cecum at the base of the tongue in man marks the site where this secretion was at one time discharged into the intestinal canal. In the present stage of human development, the thyroid is entirely an organ of internal secretion; but through its influence on other endocrine glands, it assists in maintaining reproductive and digestive functions.

The pituitary gland probably corresponds to the strainer gland in the fish stage, and in the course of development was left within the skull instead of on the side of the pharynx. It contains elements derived from the pharyngeal mucosa, and many of its tumors show pharyngeal heredity. Is it possible that this gland, which is so important in the growth of the body, is favorably affected through improved circulation by the removal of diseased adenoids and tonsils? Certainly one often sees a child of slow development, after an operation for removal of tonsils and adenoids, make a most striking physical and mental gain. The coccygeal body (gland of Luschka) has no known function, but it is connected with that stage of development in which the primitive hind or tail gut was part of the neurenteric canal. These prenatal vestiges may be the source of dermoids or neoplasms of peculiar nature, not infrequently malignant, lying in the hollow of the sacrum behind the rectum and eroding the bone. Some theorists have called the external vestigial remnants of the neurenteric canal the posterior umbilicus, and believe that the sequestration dermoids so frequently found in the lower sacral and coccygeal midline have this origin. Keith points out that the internal secretions of the five important endocrine glands, pituitary, suprarenals, gonadal, pineal and thyroid, control racial characteristics of the three great divisions of man, Caucasian, Negro and Mongol.

The sympathetic nervous system was a later development, and correlates visceral action. It stimulates the function of endocrine glands, and is in turn stimulated by their secretions. To the great English physiologist Gaskell we owe our knowledge of the involuntary nervous system. His first work on the visceral nervous system was published in the early eighties. Gaskell pointed out that certain small-calibered medullated nerves pass from the anterior horns of the spinal cord to the great sympathetic ganglion of the thorax and abdomen, which connects the central nervous system with the sympathetic. These connecting nerves enable emotions originating in the central nervous system to influence the sympathetic ganglion. From the sympathetic ganglion small nonmedullated fibers pass directly to their distribution forming the sympathetic nervous system. Gaskell also showed that there are nerves of the same kind which have visceral functions arising from the cranial nerves, and he called these parasympathetics. They are composed of the vagus nerve, the fibers in the third, seventh and ninth cranial nerves,

and the pelvic nerve from the sacral plexus. The parasympathetics are small-calibered medullated nerves with ganglion cells near their distribution, as in the heart itself and in the plexuses of Auerbach in the wall of the intestine. Neither the sympathetics nor the parasympathetics are under the control of the will, and when distributed to the same organ they follow Sherrington's law in that they are antagonistic.

Langley, who contributed much to this work, called the combined sympathetic nervous system (thoracic and lumbar ganglions) and the parasympathetic (cranial and pelvic) the autonomic system. American physiologists, especially Cannon and Crile, have contributed largely to this work. Gaskell pointed out that the sympathetic ganglions develop widespread reactions to stimuli which exercise inhibitory control over the vegetative system independent of the will, and inhibit the parasympathetics. The cerebrospinal nervous system produces conscious and accurate action of the striated muscle system, but has no control, and only indirect effect, on the nonstriated muscles. Langley, Crile, Cannon and Brown have made practical application of Gaskell's discoveries, showing how the fibers derived from the sympathetic ganglions, acting for defense, produce the most widespread and sudden effect when excited by emotions such as fear or anger. The digestive tract is temporarily deprived of function; the heart action and respiration increase in rapidity and strength, the glands of internal secretion, especially the suprarenals and thyroid, are activated, and sugar reserves in the liver and body generally are thrown into the blood stream to enable greater muscular action.

It is interesting to note that the nerves of Gaskell from the anterior horns of the spinal cord to the sympathetic ganglions are direct, and it is only those nerve fibers derived from the sympathetic ganglions themselves that pass to the various organs to produce the widespread effects spoken of, with the exception of the suprarenal gland, which receives fibers from the cord en route. The suprarenal contains within itself true nerve cells, as though at one time a start had been made for a different type of control from that which was afterward developed through the sympathetic ganglions. The parasympathetics of Gaskell, as related to the gastro-intestinal viscera, are composed of the vagus nerve derived from the bulbar division of the parasympathetics, and the pelvic nerve from the sacral plexus. When the emotions, which acting through the sympathetic system cause the sudden necessity for instantaneous use of all the body reserves, have passed away the vagus nerve comes into action and causes the heart to beat more slowly, and reduces respiration. The digestive tract, the stomach, intestine, liver and pancreas, which have been temporarily inhibited by the sympathetic fibers from the solar plexus, are stimulated to function through the vagus parasympathetic acting as a motor nerve through the plexus of Auerbach, and the pelvic parasympathetic motor nerve again permits conscious control of the bladder, sigmoid and rectum, which had been inhibited by the sympathetic fibers from the inferior mesenteric ganglion. One may well believe, however, that while these functions are checked by the sympathetic and are caused to resume action by the parasympathetics, control of their normal activities goes back to the nonstriated muscles, and the internal secretions which were the earliest forms of control. The gastro-intestinal tract is, therefore, largely con-

trolled in its functions by the nonstriated muscle and by chemical substances acting through the blood. The sympathetic ganglions act to inhibit these functions temporarily to produce rapid catabolism and spend reserves prodigally. The parasympathetics set in motion the interrupted anabolic activities and maintain reserves for future emergencies.

It may seem that these well known anatomic and physiologic details need no reiteration, and yet in my association and teaching of younger men in the profession I find that while they may know these facts, they often fail in their interpretation of them. The interpretation of the interesting phenomena which I have cited may not be correct in given instances; but if by "near-right" theories a dry subject may be made to live, the means will be justified and the strain on our memories will be less. We must not forget that memory training is the Confucian method which certainly has not led the Chinese in the paths of progress. Facts do not change. The interpretation of facts constantly changes, and new interpretations of old and new facts are the source of progress. Only as we are doubtful of our interpretations can we hope to advance scientifically.

EPIDEMIC (LETHARGIC) ENCEPHALITIS

CLINICAL REVIEW OF CASES IN THE PACIFIC NORTHWEST *

WILLIAM HOUSE, M.D.

PORTLAND, ORE.

"Westward the star of empire wends its way" setting an example that is followed with celerity by the humble but none the less busy germ. Most great epidemics have originated in the crowded centers of Europe or possibly of Asia and thence have traveled westward. On reaching the United States they have developed first on the Atlantic seaboard, within a few weeks or months have traveled to the Middle West, and within a year have invaded the Far West. The great epidemic of poliomyelitis¹ was reported in Sweden in 1905, visited the eastern part of the United States in 1907 and 1908, and came to the Pacific Northwest in 1909 and 1910, that is, between one and two years after it was reported in epidemic form in New York, Massachusetts and in general throughout the East. It had been preceded by cerebrospinal fever by two years. Later, less extensive epidemics of cerebrospinal fever traveled the same way. In 1916 and 1917 poliomyelitis was again epidemic in the Pacific Northwest following similar epidemics in the East, but the disease was much milder and cases were fewer than in 1909 and 1910. Influenza was several months in traveling from the crowded portions of the East to the West, and we had well written accounts of it as it was witnessed in the army camps of the East months before it visited the Northwest.

Epidemic encephalitis proves no exception to the rule. According to Bassoe² it first appeared in Austria in 1917, reached France and England in 1918, and in

the fall of the same year came to the United States. By the spring of 1919 cases were being reported throughout the Middle West. It reached the Pacific Northwest in October, 1919, appearing almost simultaneously in Portland, Seattle and Tacoma. Winslow³ of Seattle presented a paper which was written in the latter days of October at about the same time that I first saw cases of the disease in Portland. At a meeting of the Portland City and County Medical Society, Oct. 29, 1919, I reported four cases of this disease, two of which had already been fatal, and I have since (to December 10) examined nine more patients whom I regard as indisputably having this disease and at least four more in whom the diagnosis was open to some doubt. In each of these doubtful cases I saw the patient only once, and I do not know the later course or history.

EPIDEMIOLOGY

Except for the statements already made indicating that the disease occurs in mild epidemics, there is no hint of the method of spread. One of the most curious coincidences that I have ever witnessed occurred among my first five patients, three of whom dated their first symptoms definitely to October 12, and these three patients were separated by a distance of miles and knew nothing of one another. No two cases have occurred in the same household. None of my patients gave a history of preceding influenza, but several of them had low blood pressure and were in poor physical condition at the time of onset, suggesting that whatever the infection, the soil has to be prepared. I am convinced that the disease is not contagious in the ordinary sense of the word, and that there is no reason for quarantining patients other than keeping them isolated in their rooms away from the rest of the household, a precaution which can do no harm and may result in good.

TYPES OF THE DISEASE

Most writers say that the invasion of epidemic encephalitis is slow and deliberate. This is true in some of the cases, but by no means in all. I think I have been able to identify two types of invasion, one of which is rapid and the other slow.

Type One.—The slow type is far more common than the rapid, having occurred in ten of the thirteen cases. In this type the predominating symptoms from the beginning were double vision, slight mental confusion, at times mild delirium, followed by other symptoms which depended apparently on the particular cranial nuclei involved. After a week or ten days, the patients appeared to improve and then developed the so-called lethargy to which the disease owes its name. During this week most of them suffered from insomnia and were given some form of sedative by the attending physician. With the development of the lethargic stage, of course nothing of that kind was required.

Type Two.—This is more interesting in a way than the first type, largely because the manifestations are more dynamic. In this type, the patients complained of some head pain followed by a rapidly developing delirium, which was acute and attended by hallucinations of sight and hearing of the most vivid character.

One patient, a professor, conversed with imaginary friends and acquaintances and delivered lectures to his classes day and night for four or five days. During this time he was

* Read before the Oregon Association of Public Health Officers, Dec. 8, 1919.

¹ Owing to lack of space, this article is abbreviated by the omission of historical data and a discussion of the etiology of the disease. The complete article appears in the author's reprints.

1. House, William: Acute Anterior Poliomyelitis, Northwest Med. 2: 259 (Sept.) 1910.

2. Bassoe, Peter: Epidemic Encephalitis (Nona), J. A. M. A. 72: 971 (April 5) 1919.

3. Winslow, Kenelm: Epidemic Lethargic Encephalitis (Nona) in Seattle, Northwest Med. 18: 209 (Oct.) 1919.

unable to identify his wife or the nurse, his physician and other visitors, though when asked who a visitor was and then told the name he would say, "Oh, yes I know you, you were here this morning," or something of that sort. He was tractable, could be induced to calm himself, and gave no serious trouble to those who attended him. In rational moments, he spoke of the "hallucinations" from which he suffered and understood that they were unreal, though he mingled fact and fiction at all times. His temperature rose to 104.6 F., gradually subsiding at the end of a week, when it became practically normal. The apathetic condition did not develop until the tenth day. Throughout the illness he complained of pain in the back of the neck and back of the left ear, which was deep seated and at first thought to be due to neuritis of the occipital group of nerves. After the beginning of the apathetic stage, this pain became more troublesome, making him restless at night, and he was sensitive to touch throughout this region.

Another patient with the same group of symptoms was delirious for ten days, lost his way about the house, and talked almost incessantly, yet when spoken to declared he felt well and insisted that he must return to his work, that of salesman, because of the holiday rush.

A third patient, a woman, aged 23, suffered from the most vivid hallucinations and was so violent that she had to be restrained in a sanatorium whence she was dismissed at the end of a week, quiet though still sick. Double vision and lethargy were present. The further history of this patient is unknown to me except that she is living.

It seems to me that these two types of invasion suggest the probability that the infection may attack the brain at different points. It has been thought that the invasion is from the nasopharynx and that the germ attacks the pons and the surrounding tissues. Such an invasion would produce a reaction in a region which would cause motor nerve palsies and the type of symptoms noted in Type 1. But there is no reason that I can see why the disorder may not equally well attack the anterior part of the brain in the region of the ethmoid. In that case, there would be signs of frontal lobe irritation which would naturally produce delirium, such as was witnessed in the three cases already discussed. This delirium was of a type such as I have seen in paresis, in cocaineism and in at least two cases of rabies, in both of which necropsy revealed intense congestion and hyperemia of the anterior portions of the brain.

It is interesting to note that in two of these cases there was absence of double vision and the basilar symptoms described in the first group.

INDIVIDUAL SYMPTOMS

If I were to evaluate individual symptoms in the order of their frequency and importance, I should say that lethargy or apathy is not the most characteristic symptom. Instead I should select:

Euphoria.—This is the most striking symptom of the disease. A feeling of well-being was present in greater or less degree in every patient whom I examined. Notwithstanding unmistakable signs of grave illness, the patients seemed not to be worried by it. When asked how they felt, the patients almost invariably answered "pretty well." An Italian patient up to a few hours before his death invariably said, "Fine, fine, too many doctors," and since he had at least half a dozen he showed keen discriminating power. One patient who could not swallow and who had to be fed said she felt "pretty good," although she knew that talking was difficult and that in a way she was helpless. Even the delirium was never particularly unpleasant, seeming instead to be of a rather happy

type. With convalescence, euphoria was replaced by mild depression in a majority of cases.

Apathy.—This is a better term than lethargy as descriptive of the tendency to quiescence. It begins apparently from ten to twelve days after the onset of symptoms. The patients were never fully asleep. Their expression was blank, their attitude somewhat rigid, and in at least two cases they lay in bed with the hands flexed in a typical parkinsonian attitude. I was early impressed with the fact that the patients really were not somnolent, an idea that I have since found had already been recorded by Bassoe. Indeed, they were extremely wakeful. They lay in bed with eyes downcast or closed, face muscles rather blank and expressionless, seemingly oblivious to what went on around them. But without exception it was possible to rouse them quickly by a spoken word. Their answers were all but monosyllabic, and they then immediately lapsed into the preceding stuporous condition. They took food when offered, sometimes muttered a little, their bodies were slightly rigid, and most of them complained more or less of muscular twitching and jerking which might be anywhere in the body.

Double Vision.—This was present in eleven cases. It was a vague kind of trouble. One patient first complained that while driving a team of horses he had never seen the automobiles so crazy, all of them wanted to run over him. It was four days before he was able to describe this difficulty of sight as double vision. This double vision was present in all eleven cases during the first week, and seldom lasted more than four or five days. This point alone should differentiate the disease from tuberculous meningitis, in which double vision seldom appears before the end of the second or the beginning of the third week. The origin of the double vision in encephalitis has not been made entirely clear. Any of the oculomotor nuclei may be involved, but I was unable definitely to determine which nerve was at fault in any except one case. In that there was distinct weakness of the right sixth nerve accompanying well-marked facial, that is, seventh nerve, palsy. In the other cases I thought there was weakness perhaps of all of the oculomotor nerves. I thought the patients were unable to move the eyeballs in any direction as freely as healthy persons are able to move them. When the eyes were directed either to the left or to the right, there was no fault in the action of the muscles except that the patients found it difficult to hold them in these positions. The tendency was for the eyes to rotate back to the middle line. Nystagmus was absent. The condition suggested not a true lesion of any particular nerve, but generalized weakness of all of the nerves. In other words, there was general ophthalmoparesis rather than ophthalmoplegia. Now, since this symptom in the main lessened or disappeared after the acute stage of the disease, it seems probable that it was due to some toxic effect or possibly to generalized pressure rather than to definite hemorrhagic or inflammatory lesions of the nuclei. The positions of the images were variously such as to suggest involvement of the third, fourth and sixth nerves in different cases; but my impression is strong that the patients did not automatically converge the eyes as in ordinary focusing, though they were able partially to overcome the difficulty by an effort of will.

Nerve Changes.—Other Cranial Nerves: No patient exhibited any symptoms of involvement of the first

nerve. I examined the fundi in six cases and could detect nothing wrong with the second nerve. Ophthalmoscopic examination was difficult because of small pupils, ptosis and delirium, and fundus changes may have escaped detection. The seventh nerve was involved, causing paralysis of the muscles of expression in one case, and in this case alone could I demonstrate distinct weakness of the sixth nerve and possibly also of the fourth. The eighth nerve escaped involvement unless such auditory hallucinations as were witnessed could be attributed to it. This is not likely, as most auditory hallucinations are cortical in origin.

Fifth Nerve: Among initial symptoms in three cases was distinct pain in one cheek bone and in front of the ear. This was a dull, heavy ache accompanied by tenderness on pressure. I am at a loss to know whether this pain was due, as seems possible, to congestion or to other disturbance around the gasserian ganglion or to a lesion of the bone itself. One patient suffered from quite severe pain in the postcervical region, the origin of which may have been either in the suboccipital nerves or periosteal, that is, in the occipital bone or possibly even in the vertebra, for he was tender in these regions. Two others complained of pain in the mastoid region unattended by any demonstrable lesion of the ear drum or auditory canal. The similarity in the disturbances of the cheek bone and back of the ear is evident, but leaves doubt as to whether they were due to subacute neuritis or to osteal changes. I incline to think that all of these pains were neuritic in origin; and if this be true, the fifth nerve is involved in a considerable proportion of all cases.

Ninth and Tenth Nerves: Perhaps this was the most interesting case of the series:

A woman, aged 30, became ill with delirium and double vision. When I saw her at the end of the first week, she was wakeful, sitting up in bed. Her temperature was 102 F. and pulse rate 160. Her respirations were shallow and irregular, and her skin extremely cyanotic. There was a suggestion of exophthalmos, and I at first thought she was suffering from toxic hyperthyroidism. Her physician, Dr. R. C. Yenney, who had known her for years disagreed with me. He also said that clinically he was able to exclude any pulmonary or cardiac lesion. While one was talking to her, her eyes would close sleepily for from ten to fifteen seconds, during which time one could almost see an increase in the cyanosis. Then she would waken with a sudden start, take a few breaths, answer questions, and repeat the performance. This continued for four or five days, at the end of which time she died, apparently as a result of paralysis of the cardiac and respiratory centers.

Twelfth Nerve: This case of twelfth nerve involvement was observed:

A woman, aged 37, walked into my office, sat down, and assumed the characteristic parkinsonian attitude and seemingly went to sleep. She had visited a number of physicians, one of whom had told her husband, so he said, that she was hysterical and should get up and go about her business. I sent her home and to bed in charge of a practical nurse. She remained quiet and passive except as she was troubled by muscular twitchings. At the end of two weeks, she suddenly lost the power to swallow, found difficulty in speaking, and her body gradually became slightly rigid. She was removed to a hospital and fed through a nasal tube for several days, a method which seems better than the passing of a tube through the mouth. She remains in this rigid condition and I fear will die. Notwithstanding all these symptoms her mind is quite clear, she recalls my visits, and if they are brief reports to her husband the next day, pre-

senting a mental state which seems almost incredible when one considers the gravity of her physical condition. She has escaped few of the symptoms which characterize the disease save the early febrile stage, and even that may have been present unobserved.

Temperature Changes.—I did not see most of the patients until the end of the second week. Temperatures were reported between 101 and 103 F. in most of the cases during the first week. In the violently delirious case it rose to 104.6 only once. Two patients appeared to have been afebrile, and both of these pursued mild but characteristic courses to recovery. Fever subsided at the end of a week or ten days in most cases, though in two there was a recrudescence during the third week.

Rigidities.—In several patients the attending physician called attention to some stiffness of the neck which he thought suggested meningitis, but this rigidity was entirely different from the type found in meningitis. It was slight, easily overcome by the patient, and gave rise at most to a sense of discomfort. One patient was said by the nurse to be growing very stiff and rigid, but as a matter of fact there was no real rigidity. The muscles were more in a state of "waxy flexibility," the knee jerks were but slightly increased and ankle clonus was absent.

Skin Eruptions.—One patient during the third week of illness developed a discrete eruption consisting of about twenty pinhead sized petechiae distributed over his arms, shoulders, chest and forearms. These disappeared and were followed by two fresh crops after intervals of a week. This eruption may be of importance since it suggests the possibility that epidemic encephalitis is not a local cerebrospinal disorder but a general constitutional disease. It is not unreasonable to assume that the petechiae were due to the same agent that produced the pathologic changes in the nervous system.

Other Organs.—Involvement of viscera was conspicuous by its absence. The heart and lungs functioned normally except in two instances in which their nerve centers were involved. Only one patient had to be catheterized. There were no bedsores and no other complications.

Spinal Fluid.—Spinal puncture was done in six of the thirteen cases. In all, the fluid was germ free both in cover slip preparations and in culture. The cell count was 6, 26, 27, 46, 50 and 105, the last having occurred in the markedly delirious case described.

Leukocyte Counts.—These were made in only three of the twelve cases, and showed from fifteen to twenty thousand cells in each which corresponds in the main with the observations of others.

DIFFERENTIAL DIAGNOSIS

In typical cases the diagnosis should present no difficulty. The possibility of brain tumor and syphilis are reasonably well excluded by the relatively rapid onset and the presence of fever. Tuberculous meningitis was suggested in some of the cases, but tuberculous meningitis is commonly a childhood disease, and the paralytic phenomena are late and not early manifestations, which is true also of the delirium. Epidemic cerebrospinal fever was suggested in one case by a consultant, but I thought it could be eliminated on clinical grounds, and certainly it was promptly eliminated by spinal puncture. In the delirious cases without double vision, the onset was not unlike that

of other acute infectious diseases, and several days were required before a diagnosis could be made. Ptomain poisoning was a diagnosis made in three cases by the attending physician. All of these patients vomited for a day or two, and all attributed the vomiting to eating canned food. But as other members of the family had partaken of the same food and escaped, it seems to me that the diagnosis was not well founded. Throughout the literature many cases are being reported of cranial nerve palsies following influenza. I think it will be found that most of such cases are really cases of epidemic encephalitis.

PATHOLOGY

There has been only one necropsy among the four fatal cases, and I unfortunately did not see this. Such information as is obtainable from other writers indicates that the lesions are an increase in the cellular elements in the pia-arachnoid and cerebrospinal fluid, that throughout the brain, especially in the gray ganglions and at the base, there is a diffuse perivascular and round cell infiltration with minute hemorrhages not accompanied by necrosis. No organisms have been isolated.

PROGNOSIS AND COURSE OF THE DISEASE

Bassoe had five deaths among twelve cases. Sachs had three fatalities in one group of thirty cases, and five in a second group of fourteen cases. So far four of the thirteen patients whom I have seen have died, and one other is still in danger. Of those patients that appear to have recovered fully, one was in bed five weeks and two weeks later was still weak and tired, though able to be up about the house. Another, whose case had been diagnosed before I saw him as tuberculous meningitis, was able to come to my office in the sixth week. One whose case definitely developed in the second week of October is still bedfast and mentally confused. Of those cases that were fatal, one patient died during the second week, two patients during the third, and the remaining one in the fifth week.

TREATMENT.

The treatment must of necessity be symptomatic. Every effort should be made to reduce bodily expenditures to the lowest degree. The patients have to be encouraged to eat, and should be given an abundance of fluid and semisolid food. We are feeding one patient with a nasal tube, finding this easier than to use the ordinary stomach tube. I have given some of my patients salol or hexamethylenamin; but such treatment is empiric.

Selling Building.

Luminous Marking of Ophthalmologic Instruments.—DR. ALFRED COWAN, Philadelphia, writes: The employment of self-luminous paint in place of ordinary paint for marking optical instruments used in the dark room is an improvement. The ordinary letterings on such instruments as electric ophthalmoscopes, the meridians on trial frames, optometers and phorometers, retinoscopic trial cases, etc., are extremely difficult, if not impossible, to see in the dark room. This is all made easy by the application of self-luminous instead of the usual paint. I have had my instruments so lettered, and find that all the old difficulty has been eliminated. It is not necessary to turn on the light to see the marks, and the axes of the trial frame or the numerals on the lenses are just as plain in the total darkness as in daylight. There seem to be several grades of this paint on the market, the better kind, of course, giving greater satisfaction.

THE SIGNIFICANCE OF SOME GENERAL BIOLOGIC PRINCIPLES IN PUBLIC HEALTH PROBLEMS*

RAYMOND PEARL, PH.D.

BALTIMORE

In the year 1917 there were expended in cities of the United States having 30,000 or more inhabitants, for the general purpose of safeguarding and promoting public health, something over 120 millions of dollars. This included about 78 millions for current expenses, and about 42 millions for permanent improvements, the latter expenditure being essentially in the nature of capital outlay. These expenditures represent the interest on roughly two and a half billions, which, even in these piping times, must be conceded to be a large sum of money. Such an annual outlay of 120 millions is not a large one when reckoned per capita of the population involved, amounting to rather less than \$4 per person per year. In the aggregate, though, it is large enough fairly to raise the question as to whether those who pay the money are getting its worth in return. To propound such a question does not per se imply any carping spirit. It may be prompted simply by an honestly inquiring frame of mind, such as that which leads any sensible person to examine into his other and more apparently personal investments. Nor does an honest examination of the fundamentals of public health work imply in the slightest degree any criticism of those public servants who disburse these large sums of money. They are, by and large, sincere and earnest persons trying to do their best. The point which wants examination from time to time is that which relates to the underlying principles of public health work. Why is it done at all? Are all phases of it equally worth doing?

The motives which have led, by gradual but ever larger steps, to the expenditures of such vast sums of money to the end of improving the public health have been various, partly conscious and partly unconscious. Perhaps the chief motive finds its roots in the most fundamental of individual biologic instincts, that of the prolongation of the individual life to the greatest possible extent. With the development of general knowledge and intelligence about medical and hygienic matters, it became clear to any thinking person that two factors of high importance, to say the least, in the determination of his own individual expectation of life were: on the one hand, the kind of environment, particularly in respect of sanitation, in which he had to live; and on the other hand, the behavior, in respect chiefly of personal hygiene, of the people with whom he had to associate. The relative importance of these two factors in determining how long the average citizen was likely to live has progressively increased, at a rather alarmingly rapid rate, with the ever-increasing urbanization of the population. So long as John Doe and Richard Roe lived on widely separated farms, it mattered little to Richard if John's well came to harbor typhoid bacilli. But when both John and Richard got their drinking water from the same city reservoir, it was of vital concern to both if this supply became contaminated. Again, it was a matter of relative indifference to John if Richard had phthisis and freely exer-

* Papers from the Department of Biometry and Vital Statistics, School of Hygiene and Public Health, Johns Hopkins University, No. 9. Read before the American Society of Naturalists, Dec. 30, 1919, in a symposium on "Some Relations of Biology to Human Welfare."

cised the inalienable expectoratory rights of every freeborn citizen, so long as he could keep a mile or so away in the business of tilling his acres. But the case took on a very different aspect when both had to go to and from work in the same street car and sit side by side at the same factory bench. Then John wanted Richard coerced in respect of his personal habits. It is to attain such ends as these that we permit ourselves, if not with enthusiasm, at least with passable equanimity, to be taxed so that the great expenditures I have described may be made for public health purposes.

THE TEST OF SUCCESS OF PUBLIC HEALTH PROGRAMS

Man is easily seduced by *a priori* reasoning. Any program which can be shown to be logical, and which on a basis of logic alone seems calculated to yield desired results, will be embarked on by the vast majority of human beings with furious ardor. Only long afterward does it occur to any considerable number of people to try whether or not in fact, as distinct from logic, the program is yielding the results it was expected to. Few realize the literally awful dangers of logic. Every college student, at least, should be compelled as a prerequisite to graduation to read F. C. S. Schiller on the subject.

Now, the underlying ideas of almost any public health program are so seductively logical that it is only in the most recent times that any one has attempted in any systematic and strictly objective way to see what the program is in actual fact accomplishing. As so very often happens, it appears that there are some discrepancies between what logically ought to happen and what actually is taking place in public health work. In a broad way, the purpose of public health measures is to reduce the death rate by reducing the incidence of disease. In respect of only four causes of death can the program be regarded as having been conspicuously successful when carried out according to the *a priori* logic of the situation. These four are smallpox, typhoid fever, yellow fever, and malaria. Wherever there is a properly organized and vigorous public health service, these are now negligible causes of mortality. A fifth disease, diphtheria, might be thought worthy of inclusion, but from a public health standpoint the case is different. The great achievement with diphtheria has been in the direction of the cure, not the prevention of the disease. But what of other causes of death? In this country more people die of pulmonary tuberculosis than from any other single cause. The causal organism of this disease is perfectly well known. Yet what of its death rate? Pearson has for some years been studying pulmonary tuberculosis. In a paper recently published,¹ he brings up to date his results on the course of mortality from this disease in England during the last seventy years. Let me state his conclusions in his own words:

From '65 to about '95 there was a continuous and rapid fall in the *corrected* phthisis death rate, and also in the percentage which the deaths from phthisis were of all deaths. I further indicated that from 1895 onwards there had been a check to this rapid fall and that the curves seemed to indicate that an actual rise in the phthisis death rate might in the near future be reasonably anticipated. This view was rendered still more probable when I plotted the returns for 1910 to 1914.

He now presents diagrams down to 1918, and reaches this cautious conclusion:

On the whole, it is risky to form a very definite judgment; but having regard to the female phthisis death rate and to the percentage of the phthisis death rate on the general death rate, war difficulties do not seem to me sufficient to obscure the general trend of our graphs (as indicated before the war), namely, that somewhere about 1915 the fall in the phthisis rate which had been less rapid since 1895 would cease altogether and probably be followed by a *rise*. The next five years will show whether this be true or not. We should expect a fall in the phthisis death rate immediately, but on the average the value will remain higher than that of 1915.

Studies, as yet unpublished, which my colleague Dr. W. T. Howard has made of the phthisis death rate in Baltimore during the past ninety years, lead to substantially an identical conclusion.

I have recently² arranged the statistically recognized causes of death in an organologic classification. The results show that, comparing the two quinquennial periods, 1901 to 1905 and 1906 to 1910, the death rate from all causes assignable to the alimentary tract and associated organs concerned in metabolism fell only 1.8 per cent.

FUNDAMENTAL CAUSE OF HIGH DEATH RATES

Such results as these indicate that we are far from having attained that degree of knowledge of the causal factors in the incidence of morbidity and mortality which alone can make possible effective control. Careful study of the matter has convinced me that frank recognition and intensive investigation of the fundamental biologic factors in the problems of public health are essential to further real progress toward their solution. Time is lacking to go here into the reasons which have led to this conviction. What I shall try to do rather is to illustrate my meaning by a concrete example, not perhaps of great importance in itself, but significant as indicating the desirability of considering certain general biologic principles in dealing with public health problems.

The influenza epidemic of 1918 was unprecedented in its severity. Serious as had been earlier outbreaks of this disease, no one of them, so far as records exist, ever approached, not to say equaled, the 1918-1919 pandemic in destructiveness. If one, however, took the trouble to examine the statistics of mortality of last year's epidemic with some care, it became at once apparent that there existed an extraordinarily high degree of variation in respect of the magnitude of the death toll which different communities paid. Not only was there great variation in the rates of mortality incident to the epidemic, but also different communities exhibited marked diversities in respect of every other measurable characteristic of the epidemic, such as: (1) the general form of the mortality curve measuring the degree of explosiveness of the outbreak; (2) the maximum peak mortality rate; (3) the dates of the several mortality peaks; (4) the number of distinct mortality peaks; (5) the time elapsing between the several peaks of mortality, and, (6) the total duration of epidemic mortality.

This observed variation in the characteristics of the mortality induced by the epidemic in different localities seemed to me to constitute one of the most fundamental problems of the epidemic, and about a year ago

1. Pearson, Karl: The Check to the Fall in the Phthisis Death Rate Since the Discovery of the Tubercle Bacillus and the Adoption of Modern Treatment, *Biometrika* 12: 374, 1918.

2. Pearl, Raymond: Certain Evolutionary Aspects of Human Mortality Rates, *American Naturalist*, to be published.

I undertook an intensive investigation of the facts in about forty large American cities for which data were available by weeks.³ This study is still in progress, but certain definite results have been obtained⁴ which I should like briefly to discuss here.

The problem presented itself in clean-cut form. Why did there exist such an extraordinary degree of variation between these cities in the force of the epidemic? The epidemic was universal in its distribution, certainly in large cities. Yet some showed only a relatively slight effect of its presence in their mortality curves, while others were visited with the most appalling destruction of life. An appropriate means of attacking the problem was ready at hand in the method of multiple correlation, a method which combines certain of the most essential epistemological advantages of the experimental method with the advantage of using historical statistical records.

The most obvious point to test first was whether the differences between the several cities in the explosiveness of outbreak of the epidemic (this being the first of its biometric characteristics studied) could be accounted for by the ordinary demographic and environmental differences existing between them. An analysis of the facts relative to geographic location, age constitution of the population, density of population, and rapidity of growth of population in recent years showed immediately and conclusively that these factors had absolutely nothing to do with the variation in the epidemic. Furthermore, unpublished observations on the restrictive and repressive measures used in various communities, such as prevention of public gatherings and compulsory wearing of masks, show that none of these measures had the slightest influence on the course or severity of the mortality. Plainly the search for factors causative of the variation in epidemic mortality must be directed to channels other than those.

In a further attack on the problem, attention was turned to the normal death rates of the several cities; that is, the death rates from various causes which prevailed in these cities before the outbreak of the epidemic. The results were startling. It was found, first of all, that there was a very high correlation between the explosiveness of the outbreak of epidemic mortality and the normal death rate from all causes in the same community. This correlation was made even higher by correcting for, by making constant the chief environmental and demographic differences in the several cities.

In the make-up of the death rate from "all causes," a very small number of diseases play a preponderant part. For example, phthisis and the pneumonias alone account for rather more than a quarter of all deaths organologically classified. Approximately ten causes of death are responsible for over 65 per cent. of the total mortality. These facts at once suggest that the next step in our analysis is to find what particular causes of death are responsible for bringing about the observed high correlation between the rate for all causes and the explosiveness of the epidemic. A somewhat systematic survey along these lines was made by the method of multiple correlation.

Without going into details here, the general outcome may be thus set forth: It was found that the explo-

siveness of outbreak of influenza epidemic mortality was correlated to high degree, after correction for various environmental and demographic differences, with the three great causes of death, namely, tuberculosis of the lungs, organic diseases of the heart, and acute nephritis and Bright's disease, which are primarily dependent on the functional breakdown of one or another of the three fundamental organ systems of the body, the lungs, the heart and the kidneys. Explosiveness of outbreak of the epidemic mortality was only slightly or not at all correlated with the normal death rate from infectious diseases, such as pneumonia, endemic influenza itself and typhoid fever. Further unpublished studies have shown that the total excess mortality from the epidemic, measuring the total number of people who died, is highly correlated with our index of explosiveness of outbreak.

From a broad biologic point of view, these results seem to me to have great significance. The investigations of Pearson, as well as unpublished studies of my own, now unfortunately destroyed but susceptible of repetition, have shown with the greatest force and clearness that the incidence of pulmonary tuberculosis is determined to a very large, if not a paramount, degree by constitutional or hereditary factors rather than by environmental factors. Organic diseases of the heart, and acute and chronic nephritis are recognized by the medical profession as primarily "organic" diseases, in which the constitutional factor is regarded of relatively great importance as compared with such diseases as pneumonia or typhoid fever. Our biometric analysis demonstrates that populations particularly subject to these constitutional diseases were the populations which were least able to withstand the onslaught of an especially virulent epidemic.

The conclusion stands near at hand, not proved but strongly indicated by the evidence now available, that the primary factor in causing the observed variation between different communities, in respect of reaction to the influenza epidemic, was the biologic constitution or organic fitness of the people making up the populations of these communities. Communities in some degree organically unsound, as indicated by relatively high normal death rates from phthisis, organic heart diseases, and nephritis, were less able to meet successfully the attack of a vicious epidemic invader than were those in which these biologic conditions did not exist.

BIOLOGIC NATURE OF PUBLIC HEALTH PROBLEMS

The whole investigation seems to me to illuminate and throw into strong relief the essential point at which this paper is aimed. The great outstanding problems of public health are really broad biologic problems, which can never be satisfactorily solved until they are looked at on this basis, nor until ascertained general biologic principles have due consideration in their study. In particular, it must be recognized that heredity imposes a hard and fast limitation on the effectiveness of palliative or control measures in public health. What is particularly needed, as an essential and integral part of the science of the etiology of disease and of public health doctrine, is a basic collection of organized and digested facts regarding the inheritance of the diatheses of various important diseases, notably phthisis, the pneumonias, and heart and kidney affections. Such a body of knowledge can be acquired in only one way: by the slow, laborious, painstaking

4. Pearl, Raymond: Influenza Studies, I, On Certain General Statistical Aspects of the 1918 Epidemic in American Cities, *Pub. Health Rep.* 34: 1743 (Aug. 8) 1919.

accumulation of data regarding family histories by specially trained field workers, and the searching analysis of such records by biologists and clinicians thoroughly trained in quantitative methods of research. Investigations of this sort on tuberculosis are being actively prosecuted in my department of the School of Hygiene and Public Health of Johns Hopkins University with the support of a grant made for the purpose by the National Tuberculosis Association. It is hoped that means will be found shortly for extending this type of work to other diseases.

Broadly speaking and with some notable exceptions, the medical man has no real understanding whatever of heredity in the sense that the modern geneticist knows it. He has an infinitely less firm grasp on the matter than his forebears a century ago had. They appreciated in some degree at least the importance of the constitutional factor in the causation of disease and acted in accordance with that appreciation. Then came the wonderful development of bacteriology, which had, among its many desirable results, the unfortunate one of swinging the pendulum of medical thought far off the sound general biologic pathway. Pearson has had the good sense and the moral courage to point out in characteristically vigorous terms the consequences of the domination of too narrowly bacteriologic doctrines, so far as one particular disease, pulmonary tuberculosis, is concerned.

Whatever of blame there may be in this departure from the path of sound scientific development in the broad sense attaches by no means solely to the medical profession. The biologist is as much or more at fault. Immured in the depths of his laboratory cultivating his particular narrow specialty, he has tended to behave as though biology as a science had no concern with the problems of life. He recognizes, if compelled by cross-examination to do so, that the pressing problems of mankind—social, political, medical, public health, and all the rest—are fundamentally biologic problems. But his behavior, except in the rarest instances, does not indicate that it has ever occurred to him that if the scientific method means anything at all, he of all men should not only be able, but should also regard it as his highest privilege and duty, to contribute from that portion of the storehouse of ascertained scientific fact and principle of which he is custodian and trustee to the sound solution of these problems. If I seem to speak warmly and feelingly on this subject, it is because nearly fifteen years' experience in two of the great applied biologic sciences has led to deep convictions in my mind on this subject. When I see millions of dollars literally thrown away each year on charitable and public health activities—which every trained geneticist, if he but used the analytic powers of his mind to the same good purpose that he does in his laboratory, could demonstrate to be futile, because of the limitations which known facts of heredity place on these well-meant endeavors—I am appalled and disheartened at the spectacle science permits to be made of itself.

In less pessimistic moments, however, one finds real encouragement in the fact that, as I believe, times are slowly but steadily changing for the better in this regard. More and more it is being recognized that an intelligent interest in human and vital problems need not necessarily and automatically subject an otherwise orthodox biologist to the scorn and contumely of his professional colleagues. And furthermore, all sorts of

people, business men, labor leaders, administrators and politicians, are beginning to realize vaguely that science, and particularly biology, has discovered and knows some general principles which might, and probably practically would, be of use to them in trying to solve their problems. The biologist has made the mistake of not letting other people realize, and perhaps indeed of not himself clearly realizing, how much he is able to contribute of sound usefulness to the intellectual, social and moral welfare of mankind, as well as to his purely physical well-being. With the development of consciousness of profession, which is taking place ever more rapidly, it is confidently to be expected that his council will be more often asked, heard and heeded than has been the case in the past.

THE TEACHING OF THERAPEUTICS

HOBART AMORY HARE, M.D.

Professor of Therapeutics, Materia Medica and Diagnosis, Jefferson
Medical College of Philadelphia

PHILADELPHIA

I am writing this paper because I am hopeful that it may direct attention to what is a crying fault in medical education today, namely, the neglect of teaching students how to treat patients for the alleviation or cure of disease. I am hopeful that some good may come of it because the Council on Pharmacy and Chemistry of the American Medical Association for years past has been endeavoring to inform physicians regarding the use of proprietary products and to persuade them to prescribe drugs, proprietary or not, intelligently.

The work that the Council has done is, of course, praiseworthy in intent, and is good as far as it goes in one line, to wit, to improve medical practice among graduates; but the prime difficulty lies in the teaching of practical therapeutics to the undergraduate and to the hospital intern. This embryo practitioner in almost every medical school has no training in pharmacy, little or no training in the use of the official names of drugs or of their doses, and no training whatever in the fact that doses of different sizes, although they be of one drug, may be useless, useful or harmful, or become so after some days. He, therefore, enters practice utterly at sea when he is called on to write a prescription.

I have known of eye drops to be ordered by the quart, oleoresins mixed with aqueous solutions, powerful alkaloids, such as strychnin, put in a mixture with potassium iodid, whereby nearly all the strychnin went into the last dose, and a host of other errors too numerous to mention. I have seen a thousandth of a grain of arsenous oxid given three times a day to an adult, and a grain of atropin put in each pill; and no druggist exists who, if diplomacy did not restrain him, could not humiliate almost every physician whose recipes come to his shop. Because the medical man knows nothing of the bulk of drugs or the most efficient vehicles, or excipients, he takes the easiest way out of his dilemma and orders products already prepared, which products are often the result of much experience and scientific pharmacy.

The remedy for all this is to have every student make in a pharmacy laboratory at least one representative of each class of preparations official in the Pharmacopeia and the National Formulary. I believe that

this is done in only one school of medicine in the United States.

The young graduate, having had no experience or teaching as to doses, naturally uses doses that some commercial laboratory names. He may have been taught "doses," but he has no idea that small doses of digitalis may be useful in one case, whereas almost toxic doses may be absolutely essential in another, and so loses the patient that needed the large dose. He uses the compound mixture of licorice as a vehicle in a case of profuse bronchorrhea or threatened pulmonary edema, not knowing, or forgetting, that its most active ingredient is antimony, which is absolutely contraindicated.

When he becomes an intern in a hospital, he learns one thing of great importance, namely, that the chiefs who prescribe little and "let the patient get well" often obtain the best results; or if he is on a surgical service, the entire drug therapy may be in his hands, and the chief often boasts that he "knows nothing about drugs and don't want to." On the medical side in large hospitals he will find a hospital formulary from which mixtures are made up by the gallon with all sorts of drugs, and contradictions, with widely varying doses of the ingredients; but there is a standard dose of the whole mess whether it be for a young girl of 16 weighing 100 pounds or an old rounder weighing 200 pounds. Not only this, but these mixtures go by names which often do not mention the most active ingredient or, worse still, go by numbers, so that the order on the treatment card reads: "No. 23, dessert-spoonful t. i. d."

The fault does not stop with internship. Never having been taught practical therapeutics, the man steps into practice a fair mark for the loquacious traveling salesman who places him in the vocative by being familiar with what he ought to know. Some years ago, telling a distinguished ex-President of the Association that a patient was getting acetphenetidin, I found he did not know it was phenacetin. When he was told that the first term was the official one, he laughed and admitted that he had asked a student what he would use in a given case, and the reply was "phenol." The clinician "long" on pathology but "short" on therapeutics then informed the astonished youth that "phenol was no doubt very good, but carbolic acid was better."

PROPER METHOD OF TRAINING THE STUDENT

The remedy for the state of affairs just described is in teaching and experience when a student. This, in my experience, which is a fairly large one, is best accomplished by having the student, in his course, not only taught doses by rule of thumb, but also given the opportunity to prescribe for suppositive or actual cases, and to see the results of his order, both as to the prescription itself and as to its effect on the patient. Under the direction of an assistant professor the whole class may attend a therapeutic conference, or quiz, on the treatment of a given class of diseases, and during the conference several of the men who advise plans of treatment are called to blackboard to put in black and white what they have suggested. When they have finished, the instructor, who has continued his quiz in the meantime, criticizes the pharmacy, the doses, the form, the combinations, the therapeutics and the quantity in the whole prescription, as well as the Latin.

The number of occasions on which such criticisms lead to howls of delight at the discomfort of the man at the blackboard may be subversive of discipline, but all hands remember how John Jones wrote for nitrohydrochloric acid, iodid of potassium, tincture of gentian and tincture of iron in a quart of water, particularly if the mixture is prepared forthwith.

This large class teaching is driven home by a junior teacher taking the class in sections and having it spend one or two hours a week for several weeks writing prescriptions, for suppositive cases, which are then criticized, and the writer asked to give his reasons for using each remedy.

The regular medical ward classes should emphasize therapeutics; and, in addition, clinical, not laboratory, pharmacology should be taught. This is done by demonstrating a case of auricular fibrillation both at the bedside and with the electrocardiograph, and then giving full doses of digitalis, a second demonstration revealing the effects. So, too, the mode of action of atropin in partial or complete heart block is demonstrated, and the effects of nitrites in lowering pressure are taught by seeing a patient today with high pressure and again at the next visit with a reduced pressure. Any number of these therapeutic demonstrations can be made by the regular ward class teacher, and made still more useful if a demonstrator of clinical pharmacology who can use the polygraph and electrocardiograph is given proper hours. By this means the student is taught how drugs act and how various doses act, entirely apart from the didactic lectures on therapeutics or the general therapeutic clinics given by the head of the department, who deals of necessity with principles and practice.

FAULTS IN PRESENT METHODS

All this seems so obviously practical that the question arises, "Why is it not done?"

The answer is that there is not time. If there is not, why not? There is not time for two chief reasons. The first is that the student is taught too much of the special part of the specialties, many of which he will never attempt to practice; and unless he takes a postgraduate course after several years in general practice, he ought not to try to practice. At present the young graduate can talk learnedly of the difference between paralytic and concomitant squint or about the Bárány test, but is stumped when told to write a recipe for diarrhea.

The second reason is that the laboratory of pharmacology has drowned practical therapeutics, and has done it so effectively that in most schools literally no bedside therapeutics as a separate branch is taught, the original chair of therapeutics being filled by a laboratory pharmacologist who in some instances is not even a doctor of medicine, or if he has the degree of M.D. has never practiced a day in his life or even been an intern in a hospital. When he attempts to tell students bedside facts, it is as if he were an astronomer trying to teach a sailor how to navigate a ship without ever having been to sea. As he lacks bedside experience, he teaches, for example, that the best treatment of fever is a combination of the cold bath and coal tar antipyretics, when every one who practices knows that this is a great error. It is enough to bring the gray hairs of Dr. Simon Baruch, the great apostle of hydrotherapy, in sorrow to the grave, and if carried out will bring many patients there.

Valuable time which should be spent at the bedside learning how to use drugs is employed in having students carry out pharmacologic technic in a course of six or eight weeks or their equivalent. It is safe to say that not one man in a thousand who takes this course becomes a pharmacologist or learns to be an efficient technician. What the student needs is not to do the experiments himself but to see them done by a man so well trained that results are produced that make a demonstration that really demonstrates the fact to be remembered. I can see no more reason for making a group of students, designed to be practitioners, make bungling experiments with a Kronecker-Bowditch heart apparatus than I can for their performing amputations and visceral operations on dogs or cats with the idea that they will become good surgeons; indeed, there is less reason. One cannot make a man who has no music in his soul a violinist in a six weeks' course, and probably it is safe to say that the majority of excellent physicians have not the qualities which produce original contributions to medical knowledge.

NEED FOR THE TEACHING OF PRACTICAL THERAPEUTICS

To quote Sir George Makins,¹ in an address to the Medical Society of Manchester:

A survey of these considerations should exert a definite influence upon the determination of the nature of the course of education best suited to the development of the doctor upon whose efficiency the happiness and health of the nation so largely depends. It is clear that for the great bulk of the profession a path must be found by which advances in science are utilized for the perfection of the art of medicine, but it cannot be possible to elevate every medical man to the position of an apostle of pure science . . .

All men are not endowed with a truly scientific spirit; the power of evolving great principles is reserved to the few, and even the correct appreciation and application of those which have been laid down is not a faculty universally enjoyed. Again, the power of reasoning, the possession of initiative and invention, and the facility of developing technical skill, are qualities very unevenly distributed amongst the class of man who adopts medicine as his profession. The reasons which lead to his choice are by no means always governed by the degree of aptitude he possesses for the calling he decides to follow. To some the science of medicine appeals; some adopt medicine from the lofty motive of desiring to benefit mankind; some boys are born to succeed to a family practice; some become students of medicine because the choice coincides with that of a friend; in some business capacity is nil; in others it is the mainspring of the future career and dominates all other feelings or aspirations. Lastly, in not a few instances the initial choice has never been made the subject of serious thought or consideration.

My point is not that there should not be teachers of pharmacology. On the contrary, there should be, because it is only by the efforts of these men that the scientific or investigative side of therapeutics can be advanced and the errors of empiricism corrected. Their existence develops those who have the talent, initiative, the power of proper deduction and the love of investigation, and their methods of thought and mode of study are examples of the highest type of medical man; but in their enthusiasm they should not forget that 999 of their pupils want to know how to make the sick well and do not want to know by personal experiments on dogs the effect, for example, of cutting the animal's sympathetic on the action of cocaine

on the eye. If this is to be taught, let the pharmacologist make the experiment and demonstrate the result.

It may be said that I do not know whereof I speak; but I do, for I was once a pharmacologist myself. In the eighties I worked in laboratory pharmacology, and taught it too, as a somewhat long list of titles in the Index Catalogue will show. I am not an iconoclast, and no one rejoices more than I do that the only pharmacologic laboratory in the United States in 1886 has been followed by two score of such laboratories from which a wealth of wonderful work has originated; but it is *postgraduate work*. I am pleading that hours now used otherwise may be employed to teach not only the theory but also the practice of therapeutics. When this is done, the work of the Council on Pharmacy and Chemistry will be helped to its completion; for when the practitioner knows how to prescribe, he will not tolerate the commercial concern that poses as his teacher.

The closing paragraph of a recent editorial² has a bearing on this subject. I have substituted the word "pharmacologist" for "physiologist," and "pharmacology" for "physiology":

It is quite possible that, as has been suggested, we are approaching the time when there will be two types of persons connected with each clinical department, namely, the clinical pharmacologist, whose chief work will be the intensive study of selected groups of cases and the instruction of students in the application of the principles of pharmacology to the elucidation of disease, and the clinician, whose chief function will be the care of the patient and the instruction of the student in the practical methods of diagnosis and treatment. Obviously, some arrangement already exists in some of our better schools. In institutions in which full time medicine has been introduced, there has been a distinct effort to appoint as heads of the clinical departments men of the investigative type. One question that Addis' discussion raises is whether in our enthusiasm for laboratory research we have not overlooked the importance of purely clinical investigation and of the type of physician that naturally tends toward this.

At present an attempt is made to make pharmacologists out of men who are going to practice medicine. A real pharmacologist is a highly educated man in physiology and chemistry, an investigator, a discoverer, and by rights a leader in the higher realms of therapeutics—one who should teach medical students how drugs can be studied and should be studied in the laboratory, and to determine fundamental facts about remedies. But to try to train the general run of students, who will never have a laboratory, to be pharmacologists without first teaching elementary practical therapeutics is somewhat like a great opera singer trying to make every one a great singer, or, as if one should attempt to make his infant son sing before he tried to teach him to walk. The use of instruments of precision necessary for the study of drugs, if taught at all, should be at the bedside. I repeat what I said above: The lack of training as to what to do, what not to do, and when to do, as to remedies, is one of the weak spots in medicine today. I firmly believe that if the present generation of students is properly taught practical therapeutics, the chief labor of the Council on Pharmacy and Chemistry will be an accomplished fact, for the right way will be the easiest way. Let us first make good physicians and from these may be sifted out those who can and want to become laboratory pharmacologists.

THE EFFECT OF FOOD RESTRICTION
DURING WAR ON MORTALITY
IN COPENHAGEN

M. HINDHEDE

COPENHAGEN, DENMARK

As I have already pointed out,¹ the blockade placed the people of Denmark in a very serious situation. We had been importing more than half of our bread cereals and a very considerable amount of corn and oil cakes for the use of domestic animals. While Denmark had only half as large a supply of rye and potatoes per capita as Germany, Denmark had proportionately twice as many domestic animals. The reason for this advantageous state of affairs was that the committee which had charge of proportioning the crops between man and animals (April 4, 1917) was converted to the newer ideas on nutrition.

1. No attention was paid to the protein minimum; it was held that this minimum was so low for man that it could not be reached, provided sufficient calories were furnished.²

2. While fat was regarded as a very valuable addition to the dietary, it was not considered as being necessary.³

3. Bran was considered to be a very valuable food, one which was well digested by man.⁴

As research had also shown that man can retain full vigor for a year or longer on a diet of potatoes and fat and for half a year or more on a diet of barley and fat,⁵ reliance was placed on our potatoes and the large barley crop, which was given to man and not to the pigs, as heretofore, with the result that the pigs died of starvation, but the people received sufficient nutrition. Furthermore, we ate all our bran ourselves. We not only ate whole rye bread, but we mixed all our wheat bran with the rye flour and were able to bake good bread in this way. The Germans were unable to bake good rye bread. Their bread was too sour and too soggy. We were fortunate in having had more than a hundred years of experience in this direction. Our principal foods were bran bread, barley porridge, potatoes, greens, milk and some butter. Pork production was very low; hence the farmers ate all the pork they raised, and the people of the cities and towns got little or no pork. Beef was so costly that only the rich could afford to buy it in sufficient amount. It is evident, therefore, that most of the population was living on a milk and vegetable diet. As the potato and barley dishes were not "to Mr. Sorenson's liking" (Danish expression) to the same degree as meat, "he" ate less than before, and hence often lost weight.

The Danish food regulation was a most interesting problem for me. It was a low protein experiment on a large scale, about 3,000,000 subjects being available. What was the result? What was the effect on the health of the people? What was the death rate? At a later time I hope to be able to report on the death rate for both sexes, at different periods of life and from

various diseases. In the accompanying table I give some data on the numbers of deaths per 10,000 population in Copenhagen, between the ages of 25 and 65 years.

Food restrictions were initiated in March, 1917, and by October, 1917, they had become very severe. Therefore, my calculations embrace a year beginning and ending October 1. I could not continue my studies after October, 1918, because of the epidemic of influenza then existing. The death rate, as is known, has decreased in the last decades, as the result of a fall in the rate for epidemic diseases and tuberculosis. The cause of these diseases being known, we are able to combat them successfully. The deaths for all other diseases have been practically the same since 1900 or even earlier than this. Placing the average for the period from 1900 to 1916 (109) at 100, the variation (ratio) is small, from 93 to 107, until food regulation began. During the year of severe regulation, it fell to 66, a decrease of 34 per cent. It would seem, then, that the principal cause of death lies in food and drink. It must be remembered in this connection that we took the cereals and potatoes from the distillers so that they

NUMBER OF DEATHS PER TEN THOUSAND MEN

* From Oct. 1, 1917, to Oct. 1, 1918.

could not make brandy, and one half of the cereals from the brewers, so that the beer output was reduced one half. Is it possible that this reduction in the output of alcoholic beverages is wholly responsible for the lower death rate? This question cannot be answered; but beyond a doubt while the lessened alcohol consumption is a great contributing factor to the lowered death rate, it is not the only one. The death rate for women has also been lowered 17 per cent. in the four year period 1910-1914. It is difficult to imagine that women consumed so much alcohol that this reduction in the death rate among women is to be charged solely to greater abstention from alcoholic beverages.

The death rate for Denmark for the year October, 1917, to October, 1918, was 10.4 per thousand. It never had been lower than 12.5 (1913, 1914). A difference in the death rate of 2.1 per thousand for a population of 3,000,000 means a saving of 6,300 lives. Hence, the saving of lives in Denmark as a result of the allied blockade was considerable.

This result was not a surprising one to me. Since 1895, when I began my experiments with a low protein diet (mostly vegetarian), I have been convinced that better physical conditions resulted from this standard of living. It may be said that a vegetarian diet is a more healthful diet than the ordinary diet. As the

5. Hindhede, M.: Skand. Arch. f. Physiol. **35**: 294.

result of extensive studies in this field I am convinced that overnutrition, the result of palatable meat dishes, is one of the most common causes of disease.⁶ I agree with McCollum⁷ that:

Lactovegetarianism should not be confused with strict vegetarianism. The former is, when the diet is properly planned, the most highly satisfactory plan which can be adopted in the nutrition of man . . . The only successful combination of natural foods or milled products for the nutrition of the animal are: (a) combinations of seeds or other milled products, tubers and roots, either singly or collectively, taken with sufficient amounts of the leaves of plants; (b) combinations of the foodstuffs enumerated under (a), taken along with a sufficient amount of milk to make good their deficiencies.

I wish to call attention to the unusual amount of bran consumed by the people of Denmark during the period of food restriction. In other countries, for example, Germany, Holland and Norway, the question was discussed whether grain should be milled to yield 70, 80, 90 or 94 per cent. of bolted flour. We not only milled our rye to 100 per cent. but, profiting by previously made experiments, we added all our wheat bran to the whole rye bread; and as we added also 24 per cent. of barley meal (milled to 95 per cent., only the coarsest shells being removed) we had more than twice the amount of bread we would have had if we had milled only to 70 per cent. As the difference in digestibility was only 9 per cent. (94—85) we got about twice the amount of digestible bread. And, be it emphasized, we could bake good bread with this mixture. People entered no complaints; there were no digestive troubles, but we are accustomed to the use of whole bread and we know how to make such bread of good quality. If further proof were needed, this war experiment on such a large scale has demonstrated that bran is excellent food.

These findings agree with those of Osborne and Mendel.⁸ These investigators found that bran is a very good food for rats, and that mixed with white flour it can take the place of meat and eggs. Their results lead me to conclude—if I may be permitted to apply results obtained on rats to human beings—that: As bran can replace meat and eggs, man should eat whole bread and not so much of the more costly foods. Mendel concludes contrariwise: As people eat enough of meat and eggs, "no practical advantage on this score can be expected by converting the entire grain into flour." In my opinion, Mendel not only overlooks the economical question, but also that there are good reasons for believing that a diet composed mostly of meat, eggs and white bread—a common diet of the well-to-do—is far from being a healthful diet. Even in the case of rats, a meat diet seems eventually to be harmful. Although rats can thrive quite well on a meat diet—which man cannot do—the young of meat fed rats seldom survive.⁹ The fact of the matter is that it is claimed that rats, like human beings, will not choose an exclusive meat diet from natural instinct. That statement does not, however, apply to the rat. Watson says, on the basis of his numerous experiments on rat feeding: "I have never seen a young rat which would look at porridge or milk if meat was available."

I have seen "human" rats who would not eat porridge when beefsteak was available! And we know that beef, in large amount, is not good food for either man or rat.

While not all readers will agree with what I have said, no one can dispute the fact that the people of Denmark have no cause to regret that during the war their diet consisted mostly of milk, vegetables and bran. If Central Europe had adopted a similar diet, I doubt that any one would have starved. It seems to me, however, that the German scientists, as represented by Rubner, have not learned anything from the war. Rubner¹⁰ writes about the "necessity of bringing the supply of live stock up to the prewar basis. . . . From what I have stated, it follows that meat products must again form an adequate proportion of our diet."¹¹ Rubner wants an abundance of meat in order that the people can be "aufgefüttert." I do not agree with him. The people must first have bread, potatoes and cabbage in sufficient quantity, and then some milk. Meat is the last requirement to be met. If the people must wait until pigs and cattle have sufficient food, they will die of starvation one year before they can get an abundance of meat.

Laboratory for Nutrition Research, Copenhagen V.

LOCAL ANESTHESIA IN NEURO-SURGERY

WITH SPECIAL REFERENCE TO ITS VALUE IN
EVULSION OF THE SENSORY ROOT OF
THE GASSERIAN GANGLION

CHARLES E. DOWMAN, M.D.

ATLANTA, GA.

Those of us who were so fortunate as to participate in the medical and surgical work in France during the recent war are often asked the question, "To what extent have the principles and practices evolved by military surgery benefited civil medicine and surgery?"

Without attempting to answer such a broad question, I wish to discuss briefly the use of local anesthesia in neurosurgery, with special reference to its application in the operative relief of trifacial neuralgia, believing that the routine use of local anesthesia in the war wounds of the central and peripheral nervous systems is responsible for its wider application in neurosurgical problems of civil life.

Local anesthesia has been used in certain selected neurosurgical operations for many years, and is therefore in no sense a method which originated during the recent war. For example, Thomas and Cushing¹ reported the removal of a brain cyst under cocaine anesthesia after four previous operations under general anesthesia had been abandoned on account of excessive hemorrhage due, presumably, to the fulness of the vessels, produced by the anesthesia. They say:

Although the undertaking was premeditated, in consequence of our previous unfortunate experience in administering general narcosis to this patient, we must confess to surprise at its successful accomplishment. Contrary to all expectations, the dura proved to be insensitive to such manipulations as were

necessary to open it freely. Only when it was put under tension or displacement was any discomfort occasioned, otherwise it seemed to be absolutely free from sensitivity.

The more general application, however, in the use of local anesthesia in operations for cranial and brain injuries as the result of war wounds was urged by Colonel Gray of the British army in 1917. Also in developing the technic which was responsible for the reduction of the operative mortality from 60 or 65 per cent. to less than 30 per cent. in head injuries with dural penetration, Cushing adopted the routine use of local anesthesia as one of the important steps in the operation.

In a very extensive experience as chief of a neurosurgical team working in the forward area during the St. Mihiel and Argonne offensives, I became thoroughly converted to the use of local anesthesia in brain and spinal cord operations. The advantages were so numerous and the disadvantages so few that I could see no reason why the practice should not be adopted more generally in the operations for neurosurgical conditions as encountered in civil practice.

Since returning to civil practice, therefore, I have used local anesthesia as a routine procedure in all neurosurgical operations, excepting those on children and on extremely nervous adults whose co-operation could not be relied on.

As an illustration of the variety of these operations, this type of anesthesia has been used successfully in subtemporal decompressions, cerebellar decompressions, drainage of brain abscess, elevation of depressed skull fractures, explorations for tumors and cysts through extensive bone-flap operations, laminectomies for spinal cord tumors, peripheral nerve operations, and operations on the gasserian ganglion for trifacial neuralgia.

With the exception of those cases in which there is evidence of greatly increased intracranial pressure, the routine administration of one-third grain of morphin hypodermically thirty minutes before the operation has been practiced. When the brain is under greatly increased pressure I have felt that it might perhaps be unwise to administer morphin on account of the fact that the medullary centers may already be more or less embarrassed by the increased pressure. Such patients have therefore been given sodium bromid, 20 grains, four times daily for several days preceding the operation. In this connection I was interested to learn in a recent conversation with Sachs of St. Louis that he gives as a routine a preliminary injection of morphin, one-eighth grain, in all brain operations, regardless of the presence of increased intracranial tension, and sees no reason why this practice should be dangerous. In handling brain injuries in France we gave morphin, one-half grain, thirty minutes before operation, and

experienced no ill effects from its use. In these cases, however, we seldom had the problem of increased pressure to deal with, as contused brain had already escaped through the open dura, thereby preventing to a certain degree the same pressure effect on the brain mass that occurs in traumatic cases with skull and dura intact.

The type of local anesthesia used is a massive infiltration with 0.5 per cent. procain, to each ounce of which have been added 15 minims of epinephrin (adrenalin) chlorid solution (1:1,000). This solution is best made up immediately before each operation. For the sake of convenience the powdered procain may be kept in capsules, each capsule containing 5 grains of the drug. The contents of one such capsule added to 2 ounces of boiling water, plus the addition of 30 minims of epinephrin solution, will give a sterile 0.5 per cent. procain-epinephrin solution of sufficient quantity for the average operation. In extensive operations, however, I have used as much as 6 ounces

of such a solution and have never noticed any toxic effects from the drug. Formerly I used a 1 per cent. solution, but later experience has convinced me that the 0.5 per cent. strength is equally as satisfactory. The infiltration is made by a long needle and Luer syringe of at least 20 c.c. capacity, the point of the needle extending just through the scalp above the galea. As the infiltration progresses, the scalp is raised by the underlying fluid and the needle can be further inserted during the injection along the line of the proposed incision. The scalp proper cannot be successfully injected. The infiltration is now extended under the galea and into the muscles in those re-

Fig. 1.—Massive infiltration of scalp and subcutaneous tissues.

gions in which muscle is present. If sufficient solution is used and at least fifteen minutes allowed to elapse before the incision is made, the patient does not complain of any pain whatsoever. As a rule no further use of the solution is necessary, provided the initial infiltration has been massive enough. The skull can be entered painlessly, and for ordinary incisions and manipulations the dura seems to be absolutely free from sensitivity. It is well known that the brain itself is devoid of painful sensations; after a painless opening has once been made, therefore, all necessary intracranial manipulations can be done without conscious perception on the part of the patient.

To one who has experienced the manifold trials that attend the average extensive operation of a neurosurgical nature under general anesthesia, and then has noted the conspicuous absence of such trials in patients anesthetized locally, the advantages of the latter method are most marked. In spite of the numerous methods devised for the control of scalp hemorrhage, this is almost always a most troublesome and dangerous factor in brain operations under general anesthesia.

The entire cranial circulation is greatly congested, which gives trouble not only in the scalp but also within the skull, where frequently there will be a persistent oozing from even the smallest vessels, the eventual control of which requires the most painstaking and time-consuming attention. Even after the control of such oozing has been effected, there is great danger of later oozing, with the formation of postoperative hematoma. With the use of local anesthesia, the epinephrin proves an effective hemostatic, so that very few clamps are required. Furthermore, instead of the tremendous congestion giving rise to troublesome hemorrhage most difficult to control, the brain circulation is normal, and such bleeding as might occur is easily and quickly controlled with little or no tendency to postoperative oozing.

The average extensive brain operation under general anesthesia is usually productive of more or less shock. The prolonged anesthesia and the loss of blood are perhaps the greatest factors in producing shock. The anesthesia is usually prolonged because of the great trouble in controlling the hemorrhage. Eliminate

careful manipulation, those portions of dura at the base of the brain where there is considerable attachment to the bone are more likely to be sensitive. For this reason, during operative procedures in these regions under local anesthesia, infiltration of the dura is sometimes necessary in order to manipulate it without producing painful sensations.

LOCAL ANESTHESIA IN TRIFACIAL NEURALGIA

Perhaps the most satisfactory operation in neurosurgery is that for the permanent cure of trifacial neuralgia. In the hands of those who are thoroughly trained in neurosurgical technic, the operative mortality in this class of patients should be nil. It is, however, one of the most difficult operations in surgery, and should not, in my opinion, be attempted by the average general surgeon.

Without discussing the many interesting features of trifacial neuralgia, I wish simply to mention the use of local anesthesia in the radical operation for this condition as an illustration of the value of the method in neurosurgical procedures. I have had the opportunity during the past few months of demonstrating the advantages of evulsing the sensory root of the gasserian ganglion under procain anesthesia over similar efforts on etherized patients, and therefore feel justified in being somewhat enthusiastic on the subject.

After a preliminary hypodermic injection of one-third grain of morphin (one-half hour before operation), a massive infiltration of 0.5 per cent. procain-epinephrin solution (according to the method mentioned above) is made in the region of the proposed incision. If the approach of Cushing is selected, the infiltration should begin just over the temporal root of the zygoma and extend as high as the level of the upper border of the pinna, and forward to the posterior border of the frontal process of the malar bone. After thorough infiltration of the skin, the needle should be inserted into and through the underlying temporal muscle so that the solution may be brought into contact with the periosteum of the skull. The skin flap is now reflected downward until the periosteum of the zygoma is exposed. In order to insure a painless resection of the latter, a thorough infiltration of the periosteum can now be done before the subperiosteal resection of the zygoma is attempted. If the fascia and muscle have been sufficiently infiltrated, the incision through these structures and the removal of sufficient underlying skull can be accomplished without pain.

It has been my experience that the dura can be gently retracted and the middle meningeal artery exposed and clipped as it emerges from the foramen spinosum without discomfort. As the mandibular branch of the ganglion is exposed, however, the patient will complain of pain. This should be anticipated by asking the patient to mention the expected painful sensation as soon as it is noticed, with the assurance that after this no further pain will be experienced. As soon as the foramen ovale is reached, the operator has an excellent guide and should then infiltrate the ganglion by inserting the needle into the third branch, injecting the nerve, and further inserting the needle along the nerve directly into the ganglion. One c.c. of solution is usually sufficient completely to anesthetize the ganglion.

From now on the operation can proceed without further pain, the third and second branches and then the ganglion itself exposed, and the sensory root evulsed without any discomfort whatsoever to the patient.

Fig. 2.—Infiltration of the periosteum of the zygoma before resection.

the one, and you thereby eliminate the other. Under local anesthesia these operations are much more quickly done, and the patient rarely ever shows evidence of shock. I have turned down an extensive bone flap and had my patient leave the table with the same pulse and blood pressure as before the operation. I have never had a similar experience with general anesthesia.

There are a certain number of patients (when first seen by the neurosurgeon) whose intracranial pressure is so great as to allow of a very narrow margin of safety in the performance of a simple subtemporal decompression. This margin is undoubtedly made narrower by a general anesthetic. Local anesthesia in such cases permits the safe performance of palliative operations.

As already mentioned, local anesthesia is not applicable to children, or to adults who are very nervous or who are in a condition of noisy delirium or turbulent restlessness. In such patients, any operation under local anesthesia is inadvisable.

Although the dura covering the vertex and lateral surfaces of the brain is insensitive to incisions and

Although I prefer the Cushing method of approach, and have always adopted it, I see no reason why the excellent operation of Frazier could not be done equally as satisfactorily under local anesthesia. The infiltration, should the Frazier approach be adopted, must

Fig. 3.—Infiltration of the gasserian ganglion, the third branch being used as a guide after exposure of the edge of the foramen ovale.

extend higher, and it should not be necessary to infiltrate the periosteum of the zygoma, as this bone is not resected.

There are two very distinct advantages in the use of local instead of general anesthesia in the performance of this operation:

The first is the marked difference in hemorrhage. The constant presence of venous bleeding in the average operation of this nature requires the repeated insertion and withdrawal of small cotton pledgets, thereby permitting the operator short intervals in which to expose the ganglion and thus necessarily prolonging the time of the operation. This bleeding, provided the middle meningeal artery has been satisfactorily dealt with, is entirely venous. (I have never understood the logic of doing a preliminary ligation of the external carotid artery in these operations—a method practiced by many surgeons, it seems.) There is no doubt that during a general anesthesia, there is a definite venous and capillary engorgement in the brain and meninges which gives rise to the above-mentioned troublesome and time-consuming hemorrhage. With the patient anesthetized locally there is a marked absence of such oozing, and as a consequence the operation proceeds without interruption, the exposed field is much clearer, there is less mopping, and the average time consumed considerably less than when the patient is etherized.

The second distinct advantage is the absence of the relatively tense dura. This is present when the patient is under the influence of a general anesthetic and interferes with the free exposure by dural retraction until cerebrospinal fluid is removed, either by nicking the dura as practiced by Frazier, or by doing a lumbar puncture as practiced by Sachs. Under a local anesthetic, the dural retraction is easy and safe without this preliminary removal of spinal fluid, which therefore does not escape until the sensory root is exposed and evulsed.

CONCLUSION

I cannot but feel that the routine use of local anesthesia in this as well as in other operations of a neurosurgical nature allows a broader margin of safety than that offered by the use of general anesthesia. If this is true, our patients should be given the benefit of the difference. My own experience in this direction has been so uniformly satisfactory that I do not hesitate in recommending the more extensive use of local anesthesia in this special class of surgical operations.

THE SURGICAL TREATMENT OF GUMMATOUS OSTEITIS OF THE SKULL*

A. W. ADSON, M.D.

ROCHESTER, MINN.

Gummatous osteitis occurs in late syphilis and involves the outer table of the skull alone, or the outer and inner tables with the dura and the brain. While the gumma may be an isolated condition, it is more likely to be associated with numerous lesions on the skull. In making an examination of these lesions, it will be found that there is a destruction of the superficial tissues with necrosis of the bone, which gives the peculiar moth-eaten appearance characteristic of this disease and affords a means of diagnosis, by roentgen ray, before the skin has broken down.

Aside from the specific treatment of syphilis, it is necessary that certain surgical measures shall be

Fig. 1 (A 211775).—Necrotic gummatous ulcer of the frontal bone, which healed in six months after treatment had been administered. At first the necrotic bone had been perforated with a gimlet, with only slight results; later the skin edges were freshened and the entire sequestrum removed.

applied to the necrotic ulcers of the skull, namely, draining the suppuration, removing the sequestrum,

* From the Surgical Section on Neurology, Mayo Clinic.
* Read before the Southern Minnesota Medical Association, Mankato, Dec. 2, 1919.

or dead bone, and stimulating granulation and epidermization over the denuded areas. Several cases have been observed at the Mayo Clinic in which the skin has been elevated over a fluctuating mass varying in size from 0.5 to 4 cm. If the fluctuating area is opened,

Fig. 2 (A 248101).—Necrotic ulcer of the frontal bone due to gummatous osteitis.

a sequestrum and pus are usually found, surrounded by roughened edges of bone. In the older lesions these fluctuating masses will open spontaneously, and pour out thick, yellowish pus, which is caused by necrosis of the superficial tissues and destruction of bone. The necrotic bone at first is very white and does not bleed when touched; but on exposure to air, it becomes discolored, and a foul-smelling necrotic ulcer of the skull follows. The ulcers do not respond to specific treatment or local applications, unless the sequestrum has been removed. The necrotic areas may persist for years until sufficient necrosis takes place to loosen the sequestrum, when granulation follows (Fig. 1).

In reviewing the literature, I found very little relative to the local treatment of this condition. Dr. C. H. Mayo,¹ in 1914, discussed the treatment of dry, exposed bone by gimlet perforation in an effort to stimulate granulation. He stated that when granulation begins to take place through these small openings, flakes of bone loosen up and come away, and in time the surface is one granulating area. Dr. Lydston,² in 1915, described a case of syphilis of the cranium and spine, in which he explored one of the gummas of the skull, removing the necrotic tissue with a rongeur until living bone was reached.

The point under consideration is that in cases in which dry bone, or necrotic, suppurative bone is exposed, as in gummatous osteitis, granulation does not take place until the sequestrum has been completely removed, regardless of the depth of the sequestrum. A child on whom I operated for brain abscess developed a wound infection, resulting in a retraction of the skin edges, and exposure of the parietal bone over an area of about 9 by 6 cm. Various dressings had

been applied with little success, when accidentally the child bumped her head, loosening the outer table of the exposed bone, which we then proceeded to lift off, thereby exposing the bleeding surface between the two tables of the skull. As soon as this was done, granulation immediately followed and the wound healed without skin graftings (Figs. 2 and 3).

In four cases of gummatous osteitis, I have since applied the same principle, that is, elevating and freshening the skin margins and removing all the necrotic bone with a chisel to a depth at which bleeding is profuse. As a rule, if the necrotic bone is removed down to the diploe, no further procedure is required. When the inner table is involved, this also should be removed. If all necrotic bone is not removed at the primary operation, it is advisable to have the patient return promptly for further operative treatment. After the removal of the sequestrum, wet dressings saturated either in a boric acid solution or in physiologic sodium chlorid solution should be applied, and if epidermization is slow, skin-grafting may be resorted to. The postoperative course of four patients operated on in the Mayo Clinic for gummatous osteitis has been entirely satisfactory.

In the first case, the patient presented a history of gummatous osteitis of eighteen months' duration. At a primary operation, numerous gimlet holes were made through the necrotic bone, producing very small buds of granulation; later, the necrotic bone was removed by the use of a chisel; this was followed by a subsequent operative procedure, when small areas of dead bone that were missed at the primary operation were removed. The patient experienced no postoperative complications, and the wound healed completely in six months.

In the second case, multiple gummas of the skull were present; the largest measured 9 by 6 cm. These were treated by removing the sequestrum and freshening the skin edges;

Fig. 3 (A 248101).—Freshening of skin edges and removal of the sequestrum in gummatous osteitis.

the smaller gummas were left undisturbed. This patient's convalescence was entirely uneventful and the wound healed in three months (Fig. 4).

In the third case, a single necrotic area of the frontal bone had been present for three years. This was treated by removal

1. Mayo, C. H.: Preparation of Dry Bony Areas for Skin-Grafting. *Ann. Surg.* 60: 371, 1914.

2. Lydston, G. F.: A Unique Case of Syphilis of the Cranium and Spine, with Remarks on Syphilitic Bone Dystrophy, *Med. Rec.* 87: 43, 1915.

of the sequestrum; at the time of the patient's dismissal the wound was in good condition and covered with granulating tissue.

In the fourth case, the patient presented a large fluctuating mass which involved the right half of the frontal bone and

Fig. 4 (A 229080).—A healed gummatous area, 9 by 6 cm., of the vertex, after the removal of the necrotic sequestrum.

was associated with an involvement of the septum. The mass was drained and the necrotic bone removed.

Local surgical treatment of gummatous osteitis depends on the size of the gumma and on whether or not the skin has been broken. In cases of very small gummas, it is unwise to open the fluctuating areas; if the gumma is 1 cm. in diameter or larger, it should be opened, the sequestrum removed, and the roughened edges curetted. In the larger exposed necrotic suppurating areas all necrotic bone should be removed, the skin edges freshened, and wet dressings applied. Specific treatment should be given in conjunction with local treatment.

The principle applied to gummatous osteitis of the skull with reference to removal of the sequestrum, or dead bone, may also be applied to areas of exposed bone in nonsyphilitic cases, since granulation will at all times be hastened by removal of the outer table of the skull.

Wood Alcohol.—The wood alcohol used in the United States is obtained chiefly from the destructive distillation of wood—hard wood, birch, beech, maple, oak, elm and alder being those most frequently used. The chief uses to which it is put are for the denaturing of grain alcohol; for various purposes in lines of common manufacture (especially as a solvent in the preparation of shellac, varnish, dyes, etc.) as an ingredient in medical and pharmaceutical preparations; in the chemical industries and as a fuel and illuminant. Only within recent years has wood alcohol become so dangerous to life and sight. Formerly it was a dark, bad smelling, bad tasting fluid which no one was tempted to drink. Later, a process was developed by which this color, smell and taste are removed. Wood alcohol, when purified in this way, looks, smells and tastes like grain alcohol, and may thus be easily substituted for it by unscrupulous persons.—*Illinois Health News*, October, 1919.

A CASE OF SYPHILIS OF THE ANTERIOR HORNS

GEORGE M. GOODWIN, M.D.

Assistant Attending Physician, Medical Division B, Saint Luke's Hospital

NEW YORK

History.—J. R., a Spaniard, aged 25, a clerk by occupation, admitted to the outpatient department, Oct. 15, 1919, gave a history of his present illness of six months' duration. The chief complaint was weakness; he complained especially of weakness of the legs. When he awoke in the morning, walking was difficult and his legs felt stiff. The stiffness diminished during the day with exercise of the muscles. Continued walking tired him a great deal, and when tired he was likely to stumble. He had no pain and he was not conscious of any sensory disturbance or mental trouble. There was no bladder or rectal difficulty; and he had no trouble in swallowing. He had lost 20 pounds in the past two years, but for the past six months his weight had been stationary.

He admitted having had gonorrhea, but denied symptoms of syphilis. Just before the onset of the present illness, he had had an abscess of the right forearm. This was incised and took six months to heal. The past history was otherwise negative. As far as he knew, no other member of his family had suffered from any similar trouble.

Physical Examination.—The patient was thin, and stood with the head bowed slightly forward. The clavicles were prominent, the scapulas were of the winged type. There had apparently been contractures of the muscles of the feet with resultant pes equinus. This interfered with the patient's gait. The general musculature was poorly developed, and there was distinct atrophy of the leg muscles. The posterior aspects of the calves, especially of the left, had become flat. There was a general fibrillary contraction of the muscles. This was most marked in the muscles of the shoulder girdle, but was present in nearly all the muscles after continued voluntary contraction and subsequent fatigue. In this way it could be induced, particularly in the biceps, triceps, glutei, and hamstring muscles. These contractions were visible on inspection, but could be demonstrated better by stethoscopic auscultation over the fibrillating muscles. Over the smaller muscles the sounds resembled those of the fetal heart.

The superficial reflexes were present: the knee, elbow and wrist jerks were absent. There was no ankle clonus, or Babinski reflex. There was no pupillary light reaction: the eye grounds were negative. Touch and temperature discrimination was unimpaired.

Results of the examination of the heart, lungs and abdomen were negative. The blood pressure was 120 and 80.

DIAGNOSIS

This case presented the symptoms of muscular atrophy and muscular fibrillation. Muscular fibrillations occur in conditions in which there is a degeneration of the cells of the anterior horns of which the motor nerves are the axons. The diseases with which it is associated are: chronic bulbar paralysis, syringomyelia, amyotrophic lateral sclerosis, and progressive spinal or neuritic muscular atrophy.

The absence of bulbar symptoms and the retention of sensory discrimination ruled out the first two of these diseases. While cases are described of amyotrophic lateral sclerosis in which exaggerated reflexes and spasticity as the result of disease of the lateral columns occurred late or not at all, the condition is probably very unusual.

The picture here seemed to correspond most accurately to that of progressive muscular atrophy, although the predominance of the atrophy in the leg muscles

suggested the Charcot-Marie-Tooth type of progressive neural atrophy.

The results of the laboratory investigations in this case were: The blood Wassermann reaction was +. The spinal fluid showed a ++++ Wassermann reaction, a cell count of 80 with 92 lymphocytes in the smear, a positive globulin reaction, and a colloidal gold curve of the taboparetic type (2.5 2.5 3 2.5 2.5 1.5 0.5 0.5).

In the face of this evidence it was apparent that this patient was suffering from a syphilitic lesion of the anterior horns. In our own experience this has been a very rare manifestation of cerebrospinal syphilis, but the question arises as to what percentage of cases of progressive spinal atrophy will resolve themselves into this class with the application of the newer diagnostic tests for neurosyphilis.

TREATMENT

The patient is now under treatment with arsphenamin intravenously and auto-arsphenamized serum intraspinally. He has had two such treatments with a diminution in the muscular fibrillation. The final result from the treatment will be reported later.

125 East Fifty-Seventh Street.

Clinical Notes, Suggestions, and New Instruments

HITHERTO UNDESCRIBED DISLOCATION OF THE PATELLA ENDWISE

JOHN W. PERKINS, M.D., KANSAS CITY, MO.
Chief Surgeon, University Hospital

Elbert B., aged 16, single, laborer at freight house, while running across the dock, Aug. 15, 1919, tried to jump over a truck but struck his right knee just above the patella smartly against the handle. He was unable to flex or extend his leg, and was immediately in considerable pain.

When examined a short time after the accident, there was found a slight abrasion of the skin 2 inches above the patella. The patella was dislocated, projecting directly toward the front of the joint, apparently endwise. Effusion into the joint was prompt and considerable. In twelve hours it was sufficient to distend the joint so that the dislocated patella was not apparent to sight.

The roentgen ray disclosed the patella dislocated in such a way that the upper end was found down between the condyles. The lower end projected forward, held by the taut patella tendon. The long axis of the patella was at right angles to its normal axis. The upper part had evidently been torn away from its attachment to the tendon of the quadriceps extensor. The leg was held in a rigid position, slightly flexed. Attempts at further flexion were extremely painful.

Under an anesthetic, an attempt was made to reduce the dislocation by manipulation. With the muscles thoroughly relaxed, the leg was flexed on the thigh, when the patella was found to return apparently to its normal place between the condyles. When the leg was extended, the patella was found in its former dislocated position. It was evident that in flexing the leg the patella was forced farther down between the condyles and turned completely over so that the anterior surface became posterior, and the posterior surface anterior. The upper end could not be dislodged from its position by any manipulation of the blood-distended joint. After two or three attempts had been made, reduction by manipulation was abandoned.

A second roentgenogram was then taken, which revealed the same position as before. The patella remained with its upper end pressed down between the condyles and the posterior surface facing downward.

Operation was performed the following day at Wheatley Provident Hospital by my assistant, Dr. L. B. Miller, assisted by Dr. H. H. Owens. The knee joint was opened by a longitudinal incision outside the patella. About 8 ounces of old blood were removed from the joint. The tendon of the quadriceps extensor was found torn loose from the upper part of the patella, and the patella was found endwise between the condyles, with the upper end directed backward toward the popliteal space. The patella was dislodged by relaxing

Dislocation of patella endwise; ligamentum patellae taut.

the quadriceps extensor muscle and hooking the finger under the patella so as to drag it upward into its normal situation, where it remained. No attempt was made to close the rent in the tendon of the quadriceps extensor. The wound was closed, and the patient made an uneventful recovery. When seen one month after the accident, he could flex the knee to a right angle and extend it to within 5 degrees of a straight line.

Cases of outward dislocation of the patella on or outside the condyle of the femur are not uncommon, and I have also seen rotary dislocations in which the patella is caught edgewise between the condyles. But an independent dislocation of the patella endwise I have neither seen before, nor can I find any reference to one in the immediate literature.

1005 Campbell Street.

AN INSTRUMENT FOR ILLUMINATION AND SUCTION IN
CERTAIN SUPRAPUBIC OPERATIONS*

ERNEST M. WATSON, A.M., M.D., BUFFALO

The difficulty encountered in obtaining satisfactory illumination within the vesical cavity in certain suprapubic operations has been experienced at times by many engaged in this field of work. From the position of the bladder, deep in the pelvis, and the tendency of the pelvic viscera to encroach on the rather limited operative area, suitable illumination from above the wound cannot always be obtained. This is particularly true as regards an adequate and continued view of the base and deeper portions of the bladder cavity.

In an effort to provide a means to overcome this rather annoying handicap to many otherwise quickly executed operative procedures, an instrument has been devised to aid in illuminating the bladder cavity, and in addition to remove by suction the urine and a certain amount of blood which accumulates therein. This instrument has been found useful during the past two years in certain suprapubic work.

In suprapubic prostatectomy, many feel that a direct view of the intravesical prostatic enlargement is not always essential, and from the nature and position of the illuminator when in place, its usefulness in this procedure is limited. In practically all other operative work on the bladder performed suprapubically, however, it may be used to advantage. In simple suprapubic cystotomy, in resection of portions of the bladder wall for ulcers, new growths, etc., as well as in the resection of diverticula and in transplantation of the ureters, its use is often a distinct aid.

The composite instrument is composed of a hollow sheath with a perforated tip (on the order of the cystoscope with the Brown curve), into which is fitted an obturator. This is inserted into the urethra and passed through into the bladder after the patient has been placed on the operating table. A strip of adhesive plaster across the thighs of the patient and

filled with water, antiseptic fluid or air, as may be desired, preparatory to the suprapubic cystotomy. By an electric cord attachment the current is now turned on, and the bladder is outlined by distention and illumination.

After the stay sutures are placed in the bladder wall, the fluid or air is allowed to escape through the instrument, and thus any undue soiling of the operative field is avoided. When the bladder is opened, there is placed a tightly fitting

Fig. 2.—Longitudinal section of pelvis, with instrument in position.

perforated cap over the light within the bladder, which serves as a protection to the bladder mucosa from any heat generated by the lamp.

The lamp filament is of adequate illumination to give a brilliant light for hours when it is burned in the air. When the bladder is opened a suction pump (the type that is usually found in any operating room is satisfactory) is attached by heavy rubber tubing to the evacuating nozzle of the instrument, and a gentle suction established. This is usually sufficient for removing all of the urine and much of the blood accumulating within the bladder. Several tips have been devised as suction terminals varying in size, shape and the number of openings.

The accompanying illustrations convey a clear idea of the form and method of use of this device.

469 Franklin Street.

Fig. 1.—Apparatus: A, hollow instrument sheath; B, perforated tip for intake of fluid; C, stopcock for regulating or closing suction; D, obturator which fits into sheath (A); E, hollow evacuating and illuminating tube which fits into sheath (A); F, perforated cap which fits over light (H); G, light attachment for electric cord; H, light.

attached to the instrument keeps it in place. The obturator is then withdrawn, and the hollow illuminating and evacuating tube is passed into the sheath and securely fastened. By a suitable stopcock any urine is withdrawn and the bladder

complete transformation from the larval stage, and twelve days for the adult mosquito to become infective, a total of thirty days to be counted back from the date of ultimate infectibility. The date to be named for the safe discontinuance of operations against the mosquito as an infecting agency would then be October 1.—*Pub. Health Rep.* 34:1972 (Aug. 29) 1919.

THE SHORT CALIPER SPLINT

ROBERT F. PATTERSON, M.D., KNOXVILLE, TENN.

The short caliper splint herein illustrated was developed by me while in charge of the orthopedic service of the U. S. Army base hospital at Fort Sam Houston, Texas. It has

Short caliper splint: front view, in use, and back view.

proved to be uniformly useful in (a) ununited fractures below the knee; (b) weak union, to guard against mishap, and (c) tuberculous or other disease of the ankle or joints of the foot when it is desired to take the weight off of the foot. The splint is intended for the treatment of ambulatory cases.

The right angled portion at the lower end is inserted into the hole in the shoe, as in the application of the long caliper splint. The shoe is now pulled on until the heel lacks about 1 inch of coming in contact with the bottom of the shoe. Next the leather cuff is snugly laced up, and following this the shoe is laced as tightly as can be comfortably borne, after the weight has been borne on the splint. The heel should now just clear the shoe, or rest lightly on it, depending on how much weight it is desired that the foot carry.

If the leg is tender, the cuff can be lined with a pad of saddler's felt glued in place. Ordinarily the patient soon becomes accustomed to the appliance, and prefers no lining except moleskin.

It will be seen that the principle is the same as that of the long caliper, except that this splint takes its bearing surface, as in the case of an artificial leg, from the head of the tibia and fibula, and to a less extent from the entire surface of the leg beneath the cuff, owing to the shape of the leg.

This appliance has these advantages over the long caliper in fractures below the knee: (a) It is inconspicuous, and can be worn under the trousers; (b) it leaves the knee free and thereby prevents stiffness due to immobilization of this joint, and (c) in addition to removing the weight from a fractured bone, it acts as an effectual splint through the medium of the close fitting leather cuff, reinforced by the side irons.

AN IMPROVED DEVICE FOR ARNOLD STERILIZATION*

WILLIAM H. BARNES, A.M., BERKELEY, CALIF.

Large classes in bacteriology necessitate the provision of a good deal of modern and efficient equipment. One of the difficulties with which we have had to contend is the provision of a sufficient number of usable sterilizers, particularly gas heated sterilizers. Although we have enough when they are all in running order, keeping them in good repair has given rise to no little trouble and expense. The gas back-fires, and burns in the air chamber of the burner where the air and gas are mixed. This gives less heat units per unit of gas consumed, and results in the production of soot, which collects on the support below and which is scattered about the room. The reservoirs require frequent attention lest they become dry and burn out, notwithstanding the fact that in our laboratory they are filled automatically by siphons, an arrangement devised by Professor Hall.¹ The siphons occasionally clog or become empty and fail to maintain a constant water level.

The device here described, which was installed recently in our laboratory, eliminates these difficulties, reduces the cost of maintaining the process of sterilization, and shortens it.

This device, which is shown in the accompanying illustration, consists of a separate one-half inch pipe (*tp*), with a steam valve (*v*) carrying live steam from a central source, supplied by the main line steam pipe (*S*), to the main compartment (*C*) of each Arnold. A small opening, one-half inch in diameter, is cut in the base (*b*) of the main compartment (*C*), and the tapping pipe (*tp*) is made with an elbow to turn vertically upward into the opening just below the perforated shelf. When the steam is turned on, the temperature immediately rises to 99 or 100 C., never going above 100 C. This result obtains because the compartment (*C*) of the Arnold is not air-tight, and thus the steam cannot be confined under pressure. Part of the condensed steam falls into the reservoir (*R*) below, thus requiring that it be

An improved device for Arnold sterilization.

drained instead of being filled with water. Drainage is accomplished very easily by a connection with a nearby drain pipe.

* From the Department of Pathology and Bacteriology, University of California.

1. Hall, T. C.: Automatic Water Level for Arnold Sterilizers, *J. Bacteriol.* 3:7 (Jan.) 1918.

With this device, we have established an efficient method of Arnold sterilization which combines cheapness, cleanliness, expediency and safety. It is economical because there are no burned out Arnold sterilizers to be repaired, the live steam from a central supply source is cheaper than gas, and there are no gas plates to burn out and be repaired. It is clean because there are no burners to backfire and thus no soot to be spread about. It is expedient because the required temperature is obtained within one minute instead of requiring fifteen or twenty minutes as with the gas heating method. Last, but not necessarily least, there is no danger from fire or overheating in case the Arnold becomes dry, as it is liable to do when in charge of a careless student.

For these reasons, we feel that we have a more efficient device than the old type of gas heated Arnold.

THE VALUE OF BACTERIAL VACCINES IN IMMUNIZATION AND THERAPY

A. M. MOODY, M.D., CHICAGO

During such an epidemic as is now in progress, many physicians become panicky and jump at anything that seems to give promise of preventive and curative possibilities. As a result, commercial houses and laboratories are reaping a financial harvest through the sale of products which could do no good and may do harm. Thus vaccines are being used by many physicians without a proper understanding of the action of such forms of treatment.

In THE JOURNAL last week was an editorial on "Influenza" which calls attention to the prevailing impression regarding specific preventive and therapeutic measures in this disease. It says: "It is doubtful whether such measures exist and also whether they will be discovered in time to demonstrate their virtues in connection with the present conditions. This is especially true when we consider that the bacteriology of these infections varies in different parts of the country and that different persons react in different ways to different bacteria." These statements, I believe, should be discussed more fully, as they have an important bearing on vaccine therapy and preventive measures in other diseases of known and questionable bacterial etiology.

Bacterial vaccines consist of suspensions of killed bacteria in salt solution, oil (lipovaccines) or water, usually with a small amount of preservative, phenol or tricresol, added. There are two kinds: "stock" and "autogenous."

Stock vaccines are those made from laboratory strains of bacteria isolated from patients some time previously. Many of these strains have been grown on artificial mediums for several years.

Autogenous vaccines contain the organisms isolated from the disease process present in the patient for whom the vaccine is made.

GENERAL POINTS ABOUT VACCINES

1. A vaccine is never an emergency form of treatment: it is not indicated in acute, generalized infections.

2. Autogenous are undoubtedly better than stock vaccines for therapeutic purposes:

(a) They contain a growth of the strain of organisms causing or at least associated with the trouble.

(b) They are freshly prepared.

(c) Their antigenic properties are greater.

(d) Their toxic properties are less.

(e) Organisms isolated and made into a vaccine as soon as possible after being removed from the human body usually have greater immunizing properties.

3. As a rule, vaccines prepared four months or more prior to the time when needed should not be used:

(a) Their antigenic or immunizing properties are low.

(b) Their toxic properties are high (a and b can best be demonstrated in *B. coli* and *B. typhosus* vaccines).

(c) They may split up even to the point at which they are devoid of either antigenic or toxic properties and are practically inert.

4. There is a question as to their specificity. Many authorities and clinicians believe that bacterial vaccines are specific

in their action, that is, they cure the disease in question by the production of specific immune bodies. There are also those who go to the other extreme and believe that vaccines are absolutely valueless as therapeutic agents. Some of the former use vaccines for every disease caused by bacteria. It is probable that neither of these groups is wholly correct, since there is sufficient proof that certain diseases of bacterial origin are markedly improved following the injection of some protein material foreign to the particular specific bacteria in question. On the other hand, there is ample evidence that specific bacterial antigens in a limited number of sub-acute and chronic infections are valuable and do yield excellent results.

5. Vaccines when indicated should not be used to the exclusion of other forms of medical, surgical or general management. It is a mistaken idea that a vaccine used alone is a cure. A vaccine should be considered as an adjuvant and used always in addition to other forms of therapy and management indicated in the case in question.

6. According to my experience, vaccines are of value in the treatment of: (a) furunculosis and localized abscesses; (b) acne vulgaris; (c) colon bacillus pyelitis and cystitis; (d) chronic gonorrhea and gonorrheal rheumatism; (e) chronic bronchitis, and (f) bronchial asthma of bacterial origin.

7. Vaccines have very little value if any in: (a) infections of bone and rigid walled cavities; (b) intestinal tract infection, or (c) infections of the uterus and adnexa.

8. They are contraindicated in (a) acute infections and infectious diseases; (b) septicemia and pyemia during acute stages; (c) malignant endocarditis, etc.

PERTINENT QUESTIONS ON VACCINES

It is necessary, then, to ask oneself several pertinent questions:

1. *By what method or through what channels does a given vaccine produce results?* It is supposed, and to some extent known, that foreign protein substances or cells introduced into the body of an animal will be destroyed by something within the fluids, tissues or leukocytes of that animal. Undoubtedly this substance is of the nature of a ferment. It is known that repeated injections of certain of these bodies, as certain types of bacteria, will raise the power of the animal's resistance to this particular type or cell so that large numbers may be introduced without harmful results. Furthermore, these substances seem to be specific for this particular organism. Such an animal is then considered to be immune to this type of infection.

2. *Does immunization against one organism increase the resistance to other types of infection?* There is evidence in the literature of such an occurrence, more particularly in respect to closely related organisms, as in the colon-typhoid group. This, however, varies so greatly in different persons that a positive statement cannot be made.

3. *Can all persons be so immunized?* They cannot, and this is one reason for the development of bacterial disease at a time when, according to our present knowledge, resistance should be greatest.

4. *Are all strains and types of bacteria suitable for immunizing purposes?* They are not, because many bacteria are incapable of producing any reaction on the part of the host to produce specific bodies capable of destroying these organisms. The Pfeiffer bacillus (according to Victor C. Vaughan) is one example of such an organism.

5. *How long does it take immunity or increased resistance to certain organisms to develop?* It takes from eight to ten days to several weeks and sometimes longer.

6. *How long does a given increased resistance last?* This is known to vary within very wide limits from a few weeks to years. In the streptococcus and pneumococcus group, certainly, increased resistance is of very short duration and of a low degree.

TREATMENT WITH VACCINES

In the treatment of conditions in which vaccines are indicated, a good rule to follow is to begin with a dose small enough to avoid a generalized reaction, and gradually increase

this dose to the point at which perhaps only a slight local reaction occurs. At first one may give the injections every day to determine what is the proper dose for the patient being treated. When this point is determined, one should continue to give increasing doses at three or four day intervals until one is giving at each injection not more than one billion organisms. Massive doses of killed organisms are likely to be quite toxic and produce harmful rather than beneficial results. As a matter of fact, under such conditions it is possible to lower greatly the normal resistance of the person treated.

It must be remembered also that the body cells of persons with acute infections are quite sensitive to foreign protein injections. This is important, and physicians using vaccine therapy should bear it in mind and treat such patients with caution.

In prophylactic immunization, especially against typhoid, persons with chronic malaria, tuberculosis, bronchitis, nephritis, etc., are quite likely to react so severely to the ordinary injection that harmful results not infrequently follow.

SUMMARY

Vaccines undoubtedly are of value in increasing resistance against the development of certain diseases. They have curative properties in some chronic conditions, which have been enumerated. Before applying this method, the physician should be sure that the organism used is the actual cause of the condition in question. Immunity against the majority of bacterial diseases at best develops rather slowly, is rarely great, and is usually of short duration. Vaccine therapy is never an emergency form of treatment and therefore should not be used during an epidemic.

5 South Wabash Avenue.

THE DIAGNOSIS OF PRIMARY SYPHILIS BY CULTURE

FRED W. BAESLACK, M.D., AND WILLIAM E. KEANE, M.D., DETROIT
Pathologist and Urologist, Respectively, St. Mary's Hospital

The physician engaged in extensive venereal practice is at times confronted by patients presenting a lesion of the fore-skin or penis which, on account of previous medication, such as the use of calomel ointment, calomel dusting powder, burning with acids or escharotics, or the use of antiseptics, no longer presents the typical appearance of a chancre.

An attempt to make a diagnosis by means of the dark field usually fails, as the employment of the agents indicated above eliminates *Spirochaeta pallida* from the superficial tissues of the chancre, so that even the application of a suction cup does not yield serum which discloses the spirochete on dark-field examination.

In the course of study on the cultivation of *Spirochaeta pallida*, it was found that this organism can be grown from human tissue directly, when small pieces of such tissue are planted on horse serum medium. This medium consists of normal horse serum, free from preservatives, diluted with sterile distilled water in the proportion of 3:1. The diluted serum is put into ordinary test tubes, which are closed with rubber stoppers, previously sterilized. The tubes are filled to within an inch of the top, stoppered, and heated to 60 C. for one hour in a water-bath. The following day the temperature is brought to 70 C. for one hour, and the next day the medium is heated at 70 C. until it takes on the consistency of syrup. The tubes are then stored in the refrigerator. The heating on the three successive days not only gives the medium a semi-solid consistency, but also drives the air from the medium, so that it is under a partial vacuum.

Whenever the location of the suspected sore permits, the tissue is removed by circumcision; otherwise a thin slice of tissue is removed with a razor from the edge of the lesion. The tissue is then planted, and is pushed into the medium from one half to two thirds of the length of the tube.

The tube, if taken from the refrigerator, should be warmed to body temperature before the implantation is made.

If the lips of the tube are thoroughly heated so that the surface of the medium begins to boil, the air above the

medium is sufficiently rarefied to permit replacing the rubber stopper without difficulty after inoculation.

The inoculated tubes are incubated at 37 C. from three to five days, when a few drops of the medium near the tissue are removed with a pipet to a slide for dark-field examination.

Owing to the action of other organisms introduced with the tissue, the serum above the tissue may become liquefied, and the stopper blown out because of gas production by some of the bacteria. Nevertheless the spirochetes will be found in large numbers in symbiosis with these organisms, and can be detected under the dark field by their characteristic motility.

Tissues from such doubtful cases have been planted as late as twenty-four hours after removal. These tissues had been kept, wrapped in gauze, in the ice box for that length of time, and yielded positive cultures, when repeated dark-field examination of the scrapings of the fresh tissue itself were negative.

While the occasion for the procedure outlined may be rare, it will be found worthy of trial, especially since *Spirochaeta pallida* seems to remain in a viable state in the tissues for at least twenty-four hours after removal. The observation of patients, with late developments of syphilis, who never had specific treatment because the initial lesion was removed by circumcision without being recognized as specific, led us to the procedure outlined above.

Such tissues, placed in a small quantity of bouillon and the tube sealed, could no doubt be forwarded to laboratories equipped to do the necessary bacteriologic work.

USE AND ABUSE OF CATHARTICS *

(Continued from page 325)

PURGATIVE PILLS

ALOES

When prescribing a purgative pill, all that is really necessary is to order a sufficient dose of aloes. On account of its reliability, the fact that it does not lose its efficiency on prolonged use, and the relative smallness of its dose, aloes is the practically universal ingredient of cathartic pills. It is, therefore, worth while to study the peculiarities of this drug somewhat more closely.

As the odor is repulsive and the taste intensely bitter, aloes is unsuitable for administration other than in pill form. Its liquid preparations are therefore of no practical importance. Because of their nauseous odor, even its pills are disagreeable unless coated. When extemporaneous pills are prescribed, the mass should always be put into gelatine capsules.

Mode of Action.—It is a curious fact that the glucosids of which aloes is composed are inactive until they become decomposed into sugar and anthraquinon bodies, such as emodin, on which the activity of aloes depends. It is evidently because of the necessity for this change, which occurs in the intestine, that aloes is so slowly acting a purge. From eight to twenty-four hours may elapse before the effect occurs. Hence, it is generally administered at bedtime; though, as the active ingredient of so-called "dinner-pills," it is sometimes given with meals, whether before or after probably does not matter.

* This is the seventeenth of a series of articles on the pharmacology, physiology and practical application of the common laxatives and cathartics. The first article appeared October 18.

The conversion of the glucosids of aloes into the active bodies is favored by alkalis, including soap, and probably also by bile. This is the reason for the presence of an equal amount of finely powdered soap in the official pills of aloes, which contain 0.13 gm. (2 grains) of each of these ingredients. It is also believed that the activity of aloes is increased by iron salts; this is ascribed to their oxidizing tendency. Aloes is frequently prescribed in combination with iron in the treatment of anemia, as it at one and the same time antagonizes the constipating tendency of the iron and the tendency to constipation in the anemic patient. For this purpose a small dose of aloes, say from 0.005 to 0.010 gm. ($\frac{1}{12}$ to $\frac{1}{6}$ grain) might be added to each one of Bland's pills (pills of ferrous carbonate).

Aloes is a peristaltic stimulant acting chiefly on the colon. It is capable of producing purgation, when applied to raw surfaces or when given hypodermically. However, being a local irritant, it produces too much pain and inflammation to be useful as a hypodermic cathartic. When taken by a nursing woman, it may act as a purge to the babe.

Aloes has the reputation of causing collateral pelvic congestion, for which reason some consider it unsuitable for patients with hemorrhoids. However, this contraindication is certainly not absolute. Many persons who have hemorrhoids take it not only without harm but with actual benefit in the prevention of acute inflammatory disturbances by securing regular and sufficient bowel evacuation. Constipation and violent purgation must alike be avoided by the person with hemorrhoids. Patients suffering from an acute inflammatory complication of hemorrhoids are distressed by any bowel evacuation, and this distress is the greater as the evacuation is more profuse. Such patients do not tolerate active purgation of any kind, and perhaps least of all that produced by aloes.

On account of the pelvic congestion which aloes is assumed to cause, aloes is believed to be of value in amenorrhea, and to be shunned in excessive menstruation, tendency to uterine or other genital hemorrhage, and in pregnancy. While ordinary doses of aloetic pills fail when used as abortifacients, it is advisable to bow to popular prejudice, and to use for pregnant women some other cathartic, such as cascara sagrada or sodium phosphate.

Dose and Administration.—When aloes is to be used for the purpose of increasing colonic irritability in a case that is not considered one of hopelessly incurable constipation, it is best given as a "dinner pill," with meals. When it is thus given, the unit pill of aloes of 0.10 gm. (practically 2 grains, the size of the official pills) is likely to be larger than necessary, and half a dose or less may suffice. Such pills might, for instance, be thus prescribed:

	Gm.	
R Powdered aloes	1/50	gr. xxiii
Powdered soap	1/50	gr. xxiii
Mix. Make a mass, and divide into 30 capsules.		
Label: One three times a day after meals.		

If this daily dose be insufficient, the patient may be directed to use two or three of these pills, as required, and to return for another prescription when the quantity prescribed has been consumed. After regularity of bowel evacuation has been secured by means of such pills for a week or two, one dose a day is dropped weekly or monthly, as the case may permit, provided the desired effect continues; and, in this way, the cathartic habit may be avoided.

When failure of faithful and repeated trial renders it apparent that the patient seems incurably constipated,

then it is best to give him a prescription for pills of sufficient size to secure a thorough evacuation when one daily dose is taken. Such a pill is to be administered at bedtime on the day the patient has been without bowel movement. The patient may be encouraged to make an attempt at stool daily after breakfast. This, as will be seen, makes for economy in pill consumption, and expresses, at the same time, our reluctance to permit the patient to rely entirely on the action of the pills. The patient, however, should also understand that a thorough bowel evacuation every other day is entirely sufficient for most individuals.

There is little actual need for concentrated aloes preparations, as the dose of aloes usually required is sufficiently small to permit the preparation of pills of proper size. This is evidently the reason why purified aloes and the extract of aloes (which has twice the strength of aloes) were deleted from the present pharmacopeia. *Aloin*, which is a mixture of pentosids, is often active in so small a dose, average 0.015 gm. ($\frac{1}{4}$ grain), that inert powder has to be added to it to make a pill of proper size. In such a case, aloin is obviously of no advantage, as we must pay the manufacturer for removal and waste of perhaps 90 per cent. of material from aloes, most of which is far from being inert. Aloin presents advantage only in a case that would require an aloetic pill of excessive size. For such a one, a pill of aloin of 0.1, 0.2, or even 0.3 gm. may have to be prescribed.

(To be continued)

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, SECRETARY.

ANTIRABIC VACCINE (see N. N. R., 1920, p. 272).

The Gilliland Laboratories, Ambler, Pa.

Pasteur Anti-Rabic Vaccine.—The virus is prepared in accordance with the general method of the U. S. Public Health Service. One-fifth of an inch of dried cord, emulsified in 0.6 Cc. of 60 per cent. glycerine containing 0.3 per cent. trikresol is supplied. This is diluted with 2.5 Cc. of sterile physiological solution of sodium chloride which is supplied at the time of injection. The treatment consists of twenty-one to twenty-four doses, and are sent separately each day by Special Delivery. The first day dose is cord, dried 8, 7 and 6 days respectively; the second day is cord, dried 5 and 4 days respectively, and daily afterward, cords, dried 3, 5, 4, 3, 3, 2, 5, 5, 4, 4, 3, 3, 2, 2, 4, 3, 2, 2 days to completion of treatment.

PNEUMOCOCCUS VACCINE (See New and Nonofficial Remedies, 1920, p. 286).

The Gilliland Laboratories, Ambler, Pa.

Pneumococcus Vaccine Immunizing.—Contains Types I, II and III, respectively, in equal proportions, preserved by three cresols 0.25 per cent. Marketed in packages of four syringes containing 250, 500, 1,000 and 2,000 million killed pneumococci per Cc.; also in packages of four ampules containing 250, 500, 1,000 and 2,000 million killed pneumococci per Cc.

STAPHYLOCOCCUS VACCINE (See New and Nonofficial Remedies, 1920, p. 288).

The Gilliland Laboratories, Ambler, Pa.

Staphylococcus Vaccine (Albus and Aureus).—A suspension of *Staphylococcus albus* and *Staphylococcus aureus* in equal proportions, in physiological solution of sodium chloride and preserved with 0.25 per cent. three cresols. Marketed in packages of four syringes containing, respectively, 250, 500, 1,000 and 2,000 million killed bacteria in 1 Cc.; also marketed in packages of four ampules containing, respectively, 250, 500, 1,000 and 2,000 million killed bacteria in 1 Cc.

LIFE, DEATH—AND BACTERIA

The desire to prolong human life requires no defense, nor is it difficult to understand. Death is rarely a welcomed visitor in the human household; and it is quite natural that thinking minds should have occupied themselves with the possibility of averting death. As Jacques Loeb has remarked, the efforts to prolong life have resulted merely in a diminution of the chances of premature death. Modern preventive medicine has succeeded in warding off many menaces to life by conquering some of the dangerous infectious diseases and even threatening contagions. At best, however, by such accomplishments each person is merely guaranteed with greater degree of probability that he may enjoy the full usual duration of life. Death is not averted.

The students of some of the lower forms of animal life have found much encouragement for the belief that protoplasm is, in a sense, immortal. The biologist Maupas¹ had come to the conclusion, thirty years ago, that the unicellular organisms which he investigated could not continue to multiply endlessly by the method of fission which represents a common mode of reproduction in these forms. They reach a certain size, then divide in two, whereupon each fragment continues to grow to full size and then divides again. Maupas asserted that the race ran out after a time unless by the sexual process of conjugation some new strain of protoplasm was introduced into the organism. The observations of Woodruff² at Yale University indicate, however, that if the food and environmental conditions are suitable, reproduction may proceed an indefinitely long time without conjugation. Beginning in 1907, this American biologist has patiently followed the development of isolated infusoria through literally thousands of generations which have developed with the usual regularity without any protoplasmic contribution from other individuals of the species. Similar experiences have recently been

reported by Metalnikov,³ who conducted his experiments in Russia. The evidence from such sources suggests that fundamentally the living cell has an inherent capacity for renewal and multiplication indefinitely. In this sense, protoplasm appears to be immortal.

For higher forms of life, comparable results also have been reported suggesting, as was indicated recently in *THE JOURNAL*,⁴ that elemental death might be postponed indefinitely if a suitable nutrition could be attained continuously for the cells. Carrel's prolonged growth of connective tissue fragments outside of the body indicates this. Are we to assume from these diverse facts that, in the words of Loeb, death is not inherent in the individual cell, but is only the fate of more complicated organisms in which different types of cells or tissues are dependent on each other? Metchnikoff was responsible for the widespread impression that foreign organisms in the guise of certain intestinal bacteria are responsible for premature senility and death. The hope of averting old age has been encouraged by the advice to exclude the alimentary offenders from the body through a suitable regimen. Until recently the question as to whether life without bacteria is actually possible might have been seriously debated; but Loeb and Northrup⁵ have succeeded in raising aseptically nearly a hundred successive generations of fruit flies grown on sterilized food and themselves free from bacteria. Yet these animals all arrived at old age—and died.

Can it be that the metabolism itself of a complex organism determines the ultimate onset of death? Do the chemical processes in some groups of cells produce compounds detrimental to others, or does the transformation of materials gradually consume some essential substance which is not replaced? The scientist knows that the rate of a chemical reaction ordinarily is hastened when the temperature is raised, and decreased when it is lowered. Accordingly, Loeb⁵ has reasoned that if the duration of life is the time required for the completion of certain chemical reactions in the body, the duration of life may be doubled or trebled when the environmental temperature is lowered. The test of the hypothesis has been made on the aseptic flies in which the danger of accidental death by infection is excluded. The results show that the influence of temperature on the duration of life of the fly is the same as the influence of temperature on the velocity of a chemical reaction, since a lowering of the temperature by ten degrees results in an increase in the duration of life by two or three hundred per cent., and the same figure would be obtained if we investigated the effect of temperature on the time required to complete a chemical reaction.

5. Loeb, J.: Natural Death and the Duration of Life, *Scient. Month.* **9**: 578 (Dec.) 1919.

Such are the facts. Fortunately or unfortunately, our higher organisms cannot endure a lowered temperature; hence this device for prolonging existence cannot be requisitioned by man. In any event, death still appears as the natural result of life if the latter is to be conceived as the time required for the completion of a chemical reaction or series of such reactions. The problem of prolonging life thus appears to consist either in finding an antidote to the harmful products that gradually accumulate as the result of the body's metabolism, or in replacing that substance responsible for youthful condition and gradually destroyed in growth—or in both. At any rate, the bacteria no longer have the odious distinction of being the sole enemies of human longevity.

THE VOLUME OF THE BLOOD

The old practice of bloodletting was based, in many instances, on a desire to relieve what was supposed to be a condition of plethora. Even at the beginning of the Christian era in the days of Celsus, however, it was recognized that venesection should not be practiced indiscriminately. Precisely what criteria should be employed is not very clear; yet it is stated in *De Arte Medica*, Libri Octo:

The determining factor (i. e., in bloodletting) is neither the age nor the pregnant state of the patient, but rather the degree of physical strength. . . . There may arise, in connection with the operation of venesection, a number of questions which are likely to puzzle an inexperienced physician and perhaps lead him into error. . . . Is it not the very essence of our art, not merely to consider the factors of age and the pregnant state, but also to form an estimate of that other and more important factor, viz., the patient's strength, and then to decide whether it is, or is not, great enough to bear the loss of blood?¹

Strictly speaking, the assumed plethora which gave occasion for venesection assumed an increased amount of blood in the body. Modern research has indicated, however, that the volume of the circulating fluid tends to be maintained fairly constant in spite of influences tending to alter it. Pearce² has remarked that the "plethoric" conditions formerly thought to be appropriate for bloodletting were presumably in many instances cases of chronic hypertension in which there is, so far as is now known, no actual increase in blood volume.

There are, nevertheless, circumstances in which alterations in the quantity of the circulating medium actually occur. The regulatory and compensatory reactions of the organism whereby the exchange of fluids between blood and tissues should lead to an unaltered equilibrium is not always perfect. Thus the assertion that the effective volume of the blood is

reduced in shock has been made frequently of late.³ The treatment of hemorrhage involves consideration of the restoration of blood volume. The methods for estimating the volume have been indirect and difficult for clinical application. Many years ago, Bischoff⁴ applied Welcker's method of direct determination of the hemoglobin extracted from the entire body of two decapitated criminals, thereby concluding that the blood volume constitutes one thirteenth of the body weight. Such postmortem methods would obviously not carry us far in the study of the changing conditions of disease and therapy. Today one may still find values ranging from one twenty-first to one eighth of the body weight given for the blood volume of man.

Owing to the efforts of Van Slyke and Salvesen,⁵ a technic has been simplified to bring it more conveniently within the range of clinical possibility. With this, Salvesen⁶ found in experiments conducted in the Hospital of the Rockefeller Institute for Medical Research, New York, an average blood volume of 3,888 c.c. in six healthy persons ranging in age from 23 to 37 years. The extreme values represented one fourteenth and one nineteenth of the body weight, with an average of 5.95 c.c. per hundred grams. It will be interesting to learn the results of applications of this technic to the study of blood volume variations in disease. The data already obtained give some indications of what may be involved in current modes of venesection, of the limits of transfusion and infusion, and of other factors concerned in the modification of the circulating medium of man.

SPREAD OF THE SPIROCHETE OF INFECTIOUS JAUNDICE

Modern medicine has taught the importance of knowing the parasites of the animals that live in close contact with man. The louse, the flea, the mosquito and the rat are not merely disagreeable pests which disturb our comfort or damage our property; they are the often unsuspected carriers of harm—the hosts of invisible foes of mankind. Scarcely five years have elapsed since the Japanese investigator Inada and his colleagues discovered that *Spirochaeta icterohaemorrhagiae* is the cause of Weil's disease, to which the name "spirochetal jaundice" may now properly be applied. This discovery was made opportunely, as epidemic jaundice became prevalent among some of the troops of the allied nations early in the war. The rat was found to be a carrier of the parasite; and as the disease reported among soldiers of practically all nations engaged in combat was found most frequently

at the front, the rat-infested environment permitted an interpretation of the probable etiologic factors.

Spirochetal jaundice is not confined to Japan or to the fields of Flanders. As might be expected, the rat in other parts of the world has given evidence of infestation with the spirochete of this disease. Lyons, Marseilles, Barcelona, Tunis, Algiers and New York have already given scientific proofs of the same danger in their midst. London is the latest city to furnish new evidence of the widespread occurrence of the parasite in wild rats. Foulerton¹ has examined more than a hundred of these rodents at the Department of Hygiene in University College, and found at least 4 per cent. infected with the spirochete of jaundice.

The worldwide distribution of reservoirs of this spirochetal disease must now be recognized. This makes it more imperative than ever to learn the mode of transmission to man. Although spirochetal jaundice in man has been caused by rat-bite, direct infection in this manner can be excluded in practically all instances, in contrast with what happens in the genesis of rat-bite fever due to *Spirocheta morsus-muris*.² Foulerton has pointed out that although it is not quite certain whether the spirochete of jaundice has been identified in the intestinal contents of the healthy rat, it has been found in the feces of infected guinea-pigs; and its presence in the feces in cases of spirochetal jaundice in man may be assumed. He adds that the presence of the spirochetes in considerable numbers in the urine of rat-carriers is quite sufficient to insure a wide distribution in rat-infested areas. The possible rôle of insects as accessory or alternative factors in spreading infection cannot be excluded. However, as Noguchi³ has recorded a case in which the urine was actively pathogenic as late as four weeks after the onset of the disease, the convalescent stage of which commences usually at about the fourteenth day, the urine of human patients must still be looked on as a source of possible danger.

PHYSICAL DEFECTS AS REVEALED BY THE WAR

In the history of nations there are few instances in which an exhaustive survey of "the physical, mental and temperamental health" of a large group of the population has been made without selection. The medical examination made necessary by the drafting of millions of young men for the exigencies of the recent war has furnished statistics of a unique value which will afford an opportunity for an evaluation of the physique of mankind on a scale never approximated in any comparable degree. We have heard much of

late regarding the imperfections of the new race of young citizens and the large incidence of defects which have been revealed by the war-time medical examinations. It should be remembered, however, that many of the shortcomings were of minor importance to the well-being or working capacity of the individuals concerned. The army regulations have presented a standard of physical perfection far beyond that necessitated by the requirements of comfortable and useful existence. Many recorded defects were noteworthy from a military standpoint alone.

Against the criticisms of the national health and physique of American boys we may now cite the outcome of the study made of the records of about 2,500,000 men by Major Davenport and Lieutenant-Colonel Love for the Medical Department of the United States Army.¹ In the total population examined there were found 468 men defective per thousand examined. This means that over half of the men were found to be without any physical or mental blemish significant enough to be recorded. About two fifths of all the defects were of a mechanical sort, involving bones and joints. The second place is taken by sense organs, followed by tuberculosis and venereal disease. Many of the defects were remediable; some of the diseases were curable. The army experts assert that fully 90 per cent. of the defects found were not of such a nature as to interfere seriously with the man's performing services of the highest order in civil life.

It is to be regretted that the various countries in which recruits were examined under the draft could not have adopted some uniform system of examination and classification. Recently Comrie² analyzed the defects exhibited by 10,000 recruits in a district in Scotland which contained both rural and urban population. The most striking facts brought out are that approximately 50 per cent. of the recruits examined were qualified for the most strenuous kind of physical work. Among the other 50 per cent., about two fifths were capable of fairly strenuous work, a little less than this proportion were capable only of clerical duty, and about one sixth were either postponed or rejected. Although the system of classification adopted by the United States differed materially from that adopted in Great Britain and it is difficult to make an accurate comparison of the two countries as to the relative efficiency of their man power, certain points may be discussed to advantage.

A comparison of the cause of the rejections among the Scottish and American draft registrants is difficult not only on account of the different systems used but also because American statistics show extraordinary variations in different states. It is true, of course, that Comrie's figures are probably not applicable to the entire United Kingdom, though it is doubtful whether the great divergence would exist there that exists in a

3. Noguchi, Hideyo: The Survival of *Leptospira* (*Spirochaeta*) *Icterohaemorrhagiae* in Nature, Observations Concerning Microchemical Reactions and Intermediary Hosts, J. Exper. Med. **27**: 609 (May) 1918.

1. Davenport, C. B., and Love, A. G.: Defects Found in Drafted Men, Scient. Month. **10**: 1 (Jan.) 1920.

2. Comrie, J. D.: Lancet **2**: 957 (Nov. 29) 1919; abstr. J. A. M. A. **74**: 61 (Jan. 3) 1920.

country with the extent and climatic variations of the United States. There would doubtless be material differences in the causes of disability in different parts of the United Kingdom as there are here. Taking diseases of the thyroid gland as an instance, it is noted that among Comrie's Scottish recruits only 0.5 per cent. were rejected on account of goiter. These figures are comparable to those from some of our states. Indeed, in Maine only 0.3 per cent. of the recruits were rejected for thyroid disease. On the other hand, 6.2 per cent. were rejected in the District of Columbia; and in other states, Missouri and Wisconsin, for example, the percentage rejected for disease of the thyroid was high. Great discrepancies are found in connection with other diseases. It is hard to understand, for example, why only 1.07 per cent. of the Scottish recruits were rejected for pulmonary tuberculosis, while in one American state 23 per cent. of the recruits were rejected for this reason. One is forced to the conclusion that such an enormous difference in such a prevalent disease cannot be due to local variations in the incidence of the disease but must be due to variations in the methods of examination and in the interpretation of physical findings.

These figures of Comrie serve to call our attention once more to the fact that a considerable proportion of the male population is suffering from defects, many of which are preventable. Comrie's figures show that the proportion of men capable of the more strenuous forms of military duty progressively diminishes from 77 per cent. at the age of 18 to 30 per cent. at the age of 40. The American figures published so far do not touch on this particular aspect of the situation, but there is no special reason to believe that the general principle is any different in the United States than it is in Scotland. There is always danger, particularly if this country does not adopt some form of conscription, of forgetting the valuable lessons which were learned as the result of the wholesale examinations made by the draft boards and by the boards of medical officers at the camps. The particular point of view that is emphasized by these results is the necessity for a much wider application of individual preventive medicine than has heretofore been deemed necessary. The day is past when preventive medicine consisted merely in attention to water supplies, sewerage and general sanitation. The education of the public in the principles of correct living and the periodic examination of supposedly healthy individuals must become part of our creed as physicians if any great progress is to be made in the prevention of disease. While the necessity for community hygiene continues and still needs developing in many quarters, it has been clearly demonstrated that general sanitation will carry us only so far, and that the preventive medicine of the future must be concerned with the individual much more than has the preventive medicine of the past. The nineteenth century was the century of communal hygiene; the twentieth must be the century of individual hygiene.

Current Comment

SOME PUBLIC HEALTH PROBLEMS IN CENTRAL EUROPE

Only he who is blind to the tendencies of the times will fail to see the progress being achieved by that movement for public health which has been described in a measure as the socialization of medicine. Comparatively few of the long desired activities in the direction of preventive medicine have received governmental support in an authoritative way. The public health agencies carefully guard us as a nation against the attack of many infectious diseases, but most of the efforts to advance human welfare receive their initiative in the work of the individual or groups of persons organized for the common good. The war has been an impetus to put into operation many health projects that were making only slow advance in the self-satisfied days of peace. Nation-wide plans for health betterment and the conservation of human life have been launched. In England a ministry of health has at length been made a reality. It is interesting to learn, from the words of an expert, what the pressing problems of public health are in the reconstruction period of the defeated countries. In an address before the new Prussian parliament of which he has become a valued member, Professor Abderhalden¹ of Halle, widely known in this country as an energetic physiologist, has discussed the current needs with great frankness. Foremost is the desirability of improving the physiologic status of the child population. It has been undernourished physically and mentally. The mortality in childhood has increased greatly, and this ordinarily happy period of life has been robbed of its joys. One of the new plans proposed to counteract the situation aims to send children away to tolerant neutral countries for recuperation—a novel suggestion. The transport of curable tuberculous children to Switzerland, where milk is available, is included in the suggestion of a medically supervised adolescence. The improvement of the living conditions, and in particular the dietary, of the working people is likewise urgently recommended to the governmental authorities. In some regions the lack of abundant rations of a suitable sort has led to decreased output. The campaign against venereal disease seems to be needed as never before in central Europe. The freedom from governmental restraint which comes to all incipient revolutionary democracies is always liable to be attended with license of conduct. Our own national dangers from the venereal menace are by no means trivial; but, added to tuberculosis and undernutrition, the venereal diseases furnish an exceptionally serious problem. The worst features of alcoholism are expected to disappear in the United States with the establishment of permanent, nation-wide prohibition. A few months under the new regimen ought to furnish indisputable evidence as to its hygienic worth. Abderhalden sees a threat of great harm ahead for his country when once the routes of

1. An account of the address is given in the *Münchener medizinische Wochenschrift*, Oct. 3, 1919, No. 40, p. 1156.

trade are restored so that alcoholic drink can be imported or the possibility of its manufacture restored. How temperance is to be instituted in the midst of a nation which craves the return of alcohol will prove to be a problem of singular difficulty for legislatures and ministries to solve.

UNIVERSAL MILITARY TRAINING

The Wadsworth army bill, having been reported from committee, now approaches final consideration and action by the senate. Great interest has developed in the universal training feature of this bill, on which we commented last week.¹ Physicians are interested in this feature from two points of view: first, as it concerns the creation of an active medical reserve corps, and second, in its relation to the physical development of the young men of the nation. If we are to give actual field training to all of the young men of our country in future years, it will be necessary that they be physically examined before going into active training, that their health be guarded during the period of training, and that they receive periodic examination during subsequent years, so as to determine their fitness for service if need demands. At the same time as these young men are trained, it will be necessary to train the medical reserve officers who are to take care of them under military conditions. From the general point of view, the matter is one that affects the health of the entire nation. In the first place, physical examination of these young men will disclose certain defects which may be corrected, thus prolonging their lives. The period of physical training in the field will bring about increased physical stamina, which will mean a better type of man. Those who saw the results of military training on the physical condition of our selective service army need no argument as to the beneficial effects of such training. Increased stature, more erect carriage, greater muscular ability and elimination of superfluous adipose tissue were distinguishing signs of those who had had even brief periods of such training.

THE RELATION OF DIABETES INSIPIDUS TO DISEASE OF THE HYPOPHYSIS

The etiology of diabetes insipidus was for a long time shrouded in mystery. It was known that the disease was associated in many instances with injuries involving the base of the brain and with pathologic lesions occurring in that region. It was a notable fact that syphilitic lesions involving the basal region were particularly likely to be associated with diabetes insipidus. It is only in recent years, however, that a relationship between this disease and disturbances of the function of the pituitary body has been seriously considered. As studies of pituitary disease have progressed, it has been noted that polyuria is a not infrequent symptom. In dystrophia adiposogenitalis, this symptom may be pronounced; in acromegaly, both polyuria and glycosuria may be present, and in certain types of infantilism associated with pituitary disease, the passage of large quantities of urine may be an

outstanding feature. It has been noted, too, that tumors in the neighborhood of the hypophysis which exert pressure on this gland can be associated with the clinical picture of diabetes insipidus. As Pagniez¹ points out, it was only in 1913 that it was first demonstrated that the administration of pituitary extract has a decided effect in controlling the urinary output in some of these cases. Since that time a number of observers have confirmed this observation, although the administration of pituitary extract has not invariably been successful in this regard. In many of the cases the effect has been of a more or less temporary nature. Experimental work, such as that done by Harvey Cushing in this country, has likewise shown a relationship between the pituitary gland and the excretion of urine. Damage to the pituitary gland during operative procedures may result in polyuria, and ablation of the gland in animals likewise results in polyuria. These observations all tend to show that there is a definite relationship between the syndrome that we call diabetes insipidus and disease of the hypophysis, particularly the posterior lobe. The exact mechanism of the process is not yet clear. The importance of such a relationship, however, has a bearing on diagnosis, and suggests the careful roentgenographic examination of the skull in cases of this nature. Therapeutically, it suggests the administration of pituitary extract as a curative measure.

YEARS AND POWERS

The recent death of Field Marshal Sir Evelyn Wood at the age of nearly 82 recalls that the great war has furnished many contradictions of the prevalent impression that men who are subjected to severe strains and stresses in life, under a heavy burden of responsibility, are likely to break down and either suffer from nervous exhaustion or else die when comparatively young. Sir Evelyn Wood was a veteran of the Crimea; he was wounded in the assault on the Redan some sixty-five years ago, yet he took an active part in the organization of the British army during the recent war. He had served through the Indian mutiny with great distinction, receiving the Victoria Cross for bravery, served through the Ashanti war in South Africa as well as the Kaffir war and then the Zulu war, spent six years in Egypt in the strenuous post of commander of the forces in the lines of communication under Lord Wolseley, and after his retirement from the army as field marshal was active as the chairman of the Association of the City of London for organizing a territorial force. A great many distinguished military leaders have been noted for longevity. Von Moltke, who went through the strain and stress of the Franco-Prussian War fifty years ago, lived, like Sir Evelyn Wood, to be well beyond 80. Though Lord Roberts, the great English general, had been so disabled that his life was despaired of as a young man, he obtained the Victoria Cross for bravery, had been wounded a number of times, went through the Boer war, and yet was so far from exhaustion at 80 that the English government entrusted to him a large measure of responsibility for the mobiliza-

1. Universal Military Training, Current Comment, J. A. M. A. 74: 329 (Jan. 31) 1920.

1. Pagniez: Presse méd. 27:746, 1919.

tion and organization of the fighting forces on the western front. He died of pneumonia not far behind the lines in France, quite as any younger man might have done. Among the French, Clemenceau and Foch are conspicuous examples of what older men accomplished in the great emergency. The idea of exhaustion as a source of pathologic development and especially of such lack of nervous control as has been called nervous breakdown has not, therefore, been wholly confirmed by the war's experiences. It might confidently have been expected that the demands made on the human organism would surely cause collapse. However, unless there was definite predisposition, personal or hereditary, to the occurrence of serious nervous symptoms, these do not seem to have developed either in military or civil conditions in spite of the intense strain to which the war subjected many people. This was particularly true with regard to men who were well on in years when the war broke out. The war has shown that both men and women can stand more than was believed possible. It has also demonstrated that the powers of men are maintained to a greater age than has usually been conceded.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSAS

New Officers.—Washington County Medical Association at its annual meeting in Springdale, January 17, elected Dr. Richard T. Henry, Springdale, president; Dr. Ephraim G. McCormick, Prairie Grove, vice president; Dr. Nina V. Hardin, Fayetteville, of the University of Arkansas Infirmary, secretary, and Dr. William H. Mock, Prairie Grove, treasurer. —Sebastian County Medical Society at its annual meeting in Fort Smith, January 17, elected Dr. William R. Brooksher, Fort Smith, president; Dr. Dred R. Corente, Fort Smith, secretary, and Dr. Rufus F. Parks, Bonanza, treasurer.

COLORADO

Cancer Campaign.—Dr. Charles A. Powers, Denver, chairman of the Colorado committee of the American Society for the Control of Cancer, states that the committee has privately secured funds which will enable them to send the little booklet called "What We Know About Cancer" to the physicians of the state.

Course in Public Health Nursing.—The University of Colorado announces a four months' course in public health nursing under the joint auspices of the University of Colorado extension division, and the Colorado Fuel and Iron Company, to be held in Minnequa steel works and hospital, with field work in Pueblo and mining camps, from March 1 to June 21. The course consists of lectures and class recitations and field work. The tuition fee is \$25 for the course.

CONNECTICUT

Personal.—Dr. Thomas Eben Reeks, New Britain, has resigned as deputy commissioner of public health and director of the bureau of preventable diseases.

Society Meetings.—Waterbury Medical Association at its annual meeting, January 12, elected Dr. Edward W. Goodenough, president; Dr. Michael J. Lawlor, vice president; Dr. George A. Gosselin, secretary, and Dr. George O. Robbins, treasurer. —New Britain Medical Society recently gave a dinner in honor of its members who served in the United States Army or Navy during the war.

Mental Hygiene Division Established.—The department of health of Connecticut has established a division of mental hygiene and has appointed Dr. William B. Terhune, New Haven, director of that division. The Connecticut state department of health is the first in the United States to establish a division for the supervision of the care, and the enforcement of the laws, relative to the mentally afflicted.

Sanatorium Opened.—The state tuberculosis commission has issued a statement that the sanatorium at Crescent Beach for the treatment of bone and glandular troubles is opened for the receiving of patients. There are accommodations for fifty-eight patients. With a view to having every patient examined on admission, the state has been divided into districts and a physician designated to make examinations in each district. Dr. William M. Stockwell, Hartford, will make examinations for Hartford County, Dr. Cole B. Gibson, Meriden, for New Haven County, and Dr. Hugh B. Campbell, Norwich, for the eastern part of the state. Dr. Edward J. Lynch, Shelton, will have charge of Fairfield County. The examinations in Litchfield County will be conducted by Drs. Lynch, Stockwell and Gibson.

IDAHO

Health Progress.—More than \$400,000 will be expended in the next biennium for improvements at the various state institutions. Two department hospitals will be erected at a cost of \$140,000, one in the northern and the other in the southern part of the state.

Smallpox.—The state bureau of public health on January 7 asked the municipal and county officers to pass regulations requiring all children who attend school to be vaccinated for smallpox. The disease is present in twenty-six of the forty-four counties of the state.

ILLINOIS

Personal.—Dr. E. Bruce Godfrey, Springfield, has accepted a position in the Red Cross service, and expects soon to leave for his new field of work in Roumania.

Influenza.—February 1 and 2, only fifty-three influenza and six pneumonia cases were admitted to the hospital at Great Lakes, and no deaths were reported, February 2. This brings the total number of cases up to 1,403.

Sanatorium Burns.—Fire destroyed the main building of the Edwards Sanatorium, Naperville, February 1. The patients were removed to other buildings of the institution without casualty or panic. The loss is covered by insurance.

Grant for Therapeutic Research Work.—Northwestern University Department of Chemistry has received a grant of \$3,500 from the interdepartmental social hygiene fund of the United States government for the purpose of supporting research leading to the development of new metallo-organic compounds which may prove of therapeutic value in the treatment of syphilis of the central nervous system. A plan of cooperation has been worked out between the Universities of Wisconsin, Minnesota, Illinois and Northwestern whereby all pharmacologic work will be done by the first named institution and the synthesis of new compounds by Minnesota, Illinois and Northwestern in cooperation.

Illegal Practitioners Fined.—James A. Savage of Danville was arrested by the Department of Registration and Education of the State of Illinois, for practicing medicine without a license. He was found guilty by a jury and given a jail sentence of ninety days and fined \$50, the jail sentence to be suspended provided Savage secures a state license or quits practicing. In passing sentence, Judge Partlow stated that the people had a right to ask any man practicing medicine or healing to secure a state license; that the law required it and, therefore, there was no other way around it. —Mrs. Antoinetta Bolstapa of 2929 South Shields Avenue, Chicago, was arrested by the Department of Registration and Education of the State of Illinois for practicing midwifery without a license and was fined \$25 and costs. She promised to discontinue practicing in the future. —Frances Wesolowski of Blue Island was also arrested by the department and fined the minimum amount for practicing midwifery without a license.

Chicago

Influenza.—During the twenty-four hours ended February 2, only 802 cases of influenza were reported, with eighty-nine deaths from influenza and sixty-nine from pneumonia.

Vienna Thanks Chicago.—Dr. Carl Beck, secretary and manager of the Vienna Relief Fund, has received from Dr.

Adolph Lorenz, Vienna, a letter acknowledging the receipt of 250,000 crowns, to be distributed for food and clothing. Since the date of that letter, \$35,000 have been cabled to Vienna from Chicago.

Drive for Augustana Hospital.—Final arrangements for a campaign to raise \$700,000 for the Augustana Hospital between February 16 and 26 were provided at a meeting of the executive committee, January 30. Chief Justice Harry Olson is chairman, and Mrs. John A. Christianson vice chairman of the committee.

Postponement of Meeting.—Owing to the epidemic of influenza, the joint meeting of the Minneapolis Academy of Ophthalmology and Otolaryngology, the Milwaukee Oto-Laryngological Club, the Chicago Oto-Laryngological Society, and the Chicago Ophthalmological Society planned for this month has been indefinitely postponed.

Visiting Nurse Association.—The thirtieth annual meeting of the Visiting Nurse Association of Chicago was held, January 30, under the presidency of Mrs. Joseph M. Cudahy. The treasurer reported a balance of \$30,317 in the treasury. During the year ten new nurses were added to the staff. Mrs. Cudahy was reelected president.

Institute of Medicine.—At the meeting of the Institute of Medicine of Chicago, January 30, at the City Club, Dr. Victor C. Vaughan of the University of Michigan, Ann Arbor, presented a paper on "Remarks on the Chemistry of the Protein Molecule in Relation to Infection," and Dr. Karl K. Koessler spoke on "The Relations of Proteinogenous Amino Acids to Medicine."

Robert Koch Society Meeting.—The thirty-seventh meeting of the Robert Koch Society for the Study of Tuberculosis was held, January 29, under the presidency of Dr. Ethan A. Gray at the City Club. Dr. Edwin B. Tuteur spoke on "Neglected Opportunities in the Therapy of Tuberculosis;" Dr. James A. Britton on "Tuberculosis and Occupation," and Dr. Wilson Ruffin Abbott on the "Value of the Diagnostic Clinic to a Community."

Cook County Staff Appointments.—The following appointments are announced to the attending staff of the Cook County Hospital as a result of the competitive examination given by the Cook County Civil Service Commission: Diseases of children, Drs. Julius H. Hess, M. L. Blatt, Stanley Gibson, Walter F. Winholt, August Strauch and May Michael; laryngology, Dr. Samuel Salinger; ophthalmology, Drs. E. Findlay, G. F. Suker and C. G. Darling; gynecology, Drs. C. Culbertson, C. W. Barrett, H. Schmitz and W. J. Woolston; nervous and mental diseases, Drs. G. B. Hassin, L. J. Pollock, S. Krumholz and I. L. Meyers; obstetrics, Drs. D. S. Hillis, F. H. Falls, H. F. Lewis and W. G. Lee; pathology, Drs. H. G. Wells, E. R. LeCount, D. J. Davis and J. P. Simonds; skin and venereal diseases, Drs. J. S. Eisenstaedt, E. J. Zeisler, E. A. Oliver and A. W. Stillians; surgery, Drs. D. C. Straus, R. T. Vaughan, D. N. Eisendrath, V. C. David, R. W. McNealy, P. Oliver, K. Speed, H. Jackson, K. A. Meyer, W. R. Cubbins, G. L. Davenport, F. G. Dyas, F. A. Besley, G. G. Davis, H. McKenna, H. M. Richter.

INDIANA

Smallpox.—During the first twenty-four days of the year, 133 new cases of smallpox were reported to the Evansville Board of Health. The state board of health is supporting the local health board of Evansville in its action taken in excluding from school those children who have not been vaccinated against smallpox.

Personal.—Dr. Lewis R. Thompson, Lafayette, who recently accepted a position in the Public Health Service in the Philippine Islands, has been selected to establish and superintend the new marine hospital in Manila. Dr. Carleton B. McCulloch, Indianapolis, has announced his candidacy for the democratic nomination for governor.

Admits Illegal Practice.—A. W. Van Bysterweld, Warsaw, appeared in Circuit Court, January 19, and pleaded guilty to the charge of illegal practice of medicine and was fined \$25 and costs, and released on his promise to leave the state. He contended that he was not a physician but a chemist. It is said that he has been convicted on several occasions on similar charges.

Health Board Operates at Loss.—The Indianapolis board of health operated during 1919 with a deficit of approximately \$75,000, or \$3,000 greater than the deficit in 1918. This deficit was due principally to increased salaries and cost of supplies. During the year the hospital handled more than

10,000 patients. The appropriation available to the health board during 1920 is about \$327,000, and the budget will be revised in an endeavor to keep the expenditure within the appropriation.

War Service Gives Credits.—The treasurer of the Indiana State Board of Medical Registration and Examination announced, January 23, that hereafter service in the medical department of the Army, Navy or Marine Corps may be accepted as time credits for the examination to practice medicine in the state. The first examination under the new ruling will be held at the state house, Indianapolis, February 10, 11 and 12.

Influenza.—The city of South Bend has appropriated \$1,000 for use of the Visiting Nurses Association in combating influenza. The crest of the epidemic seems to have passed, as less than 100 new cases were reported, January 27. Mishawaka is said to have had seventeen deaths due to influenza since January 1. The total number of cases of influenza in South Bend is reported to have been about 2,100, with forty-seven deaths from influenza and pneumonia. The city council of Fort Wayne, January 23, appropriated \$10,000 to be used in the fight against influenza.

New Health Divisions.—Plans for the working of the two new divisions of the state board of health include the holding in each congressional district of public meetings at which the work of the divisions will be discussed. The tuberculosis division will have a director, assistant to the director, and two nurses, who will hold meetings throughout the state aiming at prevention rather than care and cure of patients suffering from the disease. The infant hygiene division will be similarly organized and will hold similar meetings; it will deal only with children of 5 years of age or younger, and will endeavor to encourage knowledge of prenatal hygiene.

MASSACHUSETTS

Home for Incurables.—The Northwestern Deaconess Association has assumed control of the Cullis Home in Roxbury and will conduct the institution exclusively for the care of persons afflicted with cancer and other incurable diseases. The institution will be known hereafter as the Palmer Home.

Out-Patient Medical Society.—At the first clinical meeting of the Out-Patient Medical Society of Massachusetts General Hospital, Boston, held January 22, Dr. Paul D. White discussed "Practical and Modern Teaching of Heart Disease," and Dr. Richard H. Miller spoke on "Errors and Shortcomings in Diagnosis."

Campaign Against Cancer.—In the campaign against cancer free diagnosis of pathologic specimens is offered to the profession of the state by Harvard Commission for Cancer Research through the commissioner of health. Pathologic specimens should be sent to the director of the state diagnosis service, Cancer Commission, Medical School of Harvard University, Boston.

Tuberculosis League.—The Massachusetts Tuberculosis League is reorganizing to carry through a more intensive campaign for the prevention of tuberculosis. This is in accordance with the plans of the National Tuberculosis Association, which is planning to raise more than \$7,000,000 throughout the country for financing the greatest drive for health education undertaken in the world's history.

Personal.—Dr. William R. P. Emerson, Boston, lectured on child nutrition in eight schools in Chicago and at the Art Institute in that city on January 22, 23 and 24. Dr. Sylvester E. Ryan, Springfield, has been nominated by the governor as a member of the state public health council, succeeding Dr. William J. Gullivan, Boston, resigned to accept the position of director of the tuberculosis sanatoriums of the state. Dr. Richard C. Cabot, Boston, has been appointed professor of social ethics in Harvard University.

Free Medical Lectures.—The annual course of free public lectures given at the Harvard Medical School, Longwood Avenue, at 4 p. m., on Sunday afternoons was inaugurated, February 1. The following is the schedule of lectures:

- Feb. 1—Dr. Richard M. Smith, Boston. Child welfare.
- 8—Edwin H. Place, Boston. Smallpox and vaccination.
- 15—Dr. Harold C. Ernst, Boston. Protection against infection in diseases other than smallpox.
- 22—Dr. Kurt H. Thoma. Diseases of the teeth in relation to systemic disturbances.
- 29—Dr. Frederick T. Lord, Boston. Pneumonia.
- Mar. 7—Dr. Percy G. Sales, Boston. Some aspects of alcohol.
- 14—Dr. W. T. Boyle. New conceptions of the structure of matter.
- 21—Dr. Cecil K. Drinker, Cambridge. Health and industry.
- 28—Dr. Channing Frothingham, Boston. Some points of interest to the public in regard to medical education as brought out by the recent war.

Plainfield Health Clinic.—A few years ago a summer resident of Plainfield conceived the idea that an annual lecture and demonstration on some health topic by a representative of the state department of health would assist in teaching certain fundamentals necessary to personal and community health. This plan has developed into a midsummer health clinic to which children, no age limit, may be brought for physical examination and for advice. Troublesome temporary teeth are extracted, children are vaccinated on request of a parent, mothers are instructed in the proper care and feeding of infants and growing children and concerning the correction of physical defects. Following the clinic session, those children requiring further examination and treatment are transported to a hospital for necessary special advice and treatment.

MARYLAND

Election.—At the regular meeting of the Baltimore County Medical Association, January 21, the following officers were elected: president, Dr. John W. Harrison, Middle River, and secretary, Dr. George S. M. Kieffer, Morrell Park.

Personal.—Dr. William H. H. Campbell, Owings Mills, was injured recently by falling on the ice.—Dr. John M. T. Finney, Baltimore, has declined the offer made him by Harvard University and will continue his connection with the Johns Hopkins Hospital and Medical School.

Typhoid Rate Low.—Despite the fact that conditions in the new annex of Baltimore city are more favorable to the spread of typhoid fever than in the older part of the city, Baltimore during the year just passed, had the lowest death rate from typhoid fever in its history. There were sixty deaths during the year from this disease, and of these fifty were among white persons and the remainder among negroes.

Eudowood Sanatorium to Expand.—Extensive improvements will be made during the present year to Eudowood Sanatorium, Towson, according to reports of the officers submitted at the annual meeting of directors in Baltimore, January 26. The greatest need is a nurses' home, which the woman's board will erect at a cost of from \$25,000 to \$30,000. Plans also will be considered for additional private rooms to the Victor G. Bloede Hospital, for an additional medical building, supplied with roentgen-ray laboratory, dental equipment and a medical library, for an additional infirmary and other improvements. Work on these will be begun as soon as weather permits. Dr. Henry Barton Jacobs, Baltimore, president of the board of directors, told of the excellent work accomplished since the institution was established, and emphasized the need for more beds for advanced cases.

Influenza on Increase.—During the week ending January 31, influenza has increased rapidly in Baltimore. January 30 the greatest number of new cases developed, 452 being reported for a period of twenty-four hours, making 1,386 cases reported to the city health department since the beginning of the present outbreak. The cases are well scattered, virtually every section of the city being affected. The severe symptoms of the outbreak of 1918 are absent, the death rate continues low, and many of the cases reported as influenza are nothing more than "ordinary colds." Pneumonia also continues on the increase, the new cases reported in one day being lobar pneumonia, twenty-three; bronchopneumonia, twenty-one; with eight deaths from lobar pneumonia and one from bronchopneumonia.—The state board of health received reports of 516 new cases in the counties for a period of twenty-four hours on the same date. Montgomery County took the lead reporting 324 cases; Prince George's County had 153, and Frederick County, eighty-three cases.—From Camp Meade came reports of 122 cases. Camp officers reported fourteen new cases for the day. Twelve cases have been reported from Fort McHenry Hospital. A small epidemic of influenza has broken out at Edgewood Arsenal, the disease having been brought to the reservation by chemical warfare troops.

MISSISSIPPI

Physician Found Guilty.—In the case of Dr. Fletcher E. Lee, Petal, charged with manslaughter as the result of performing a criminal operation, the jury is reported to have brought in a verdict of guilty, January 27.

New Officers.—At the annual meeting of the Lauderdale County Medical Association held at Meridian, January 10, Dr. Julian T. Bailey, Meridian, was elected president; Dr. Thomas G. Cleveland, Meridian, vice president, and Dr. Hiram C. Sheffield, Meridian, secretary.

Work of State Laboratory.—In the annual report of the work of the state hygienic laboratory for the biennium ended June 30, 1919, it is shown that 30,707 specimens were examined, thirty-eight patients who had been bitten by rabid dogs were treated free of charge, and 101,243 c.c. of anti-typhoid vaccine were distributed to the people of the state.

Need of Home for Feeble-minded.—The Mississippi Society for Mental Hygiene in a recent bulletin urges the need of an institution for the feeble-minded, as an economic proposition to save lives and property destroyed by feeble-minded when allowed to be at large. The hospital mental efficiency bill to be considered by the next legislature establishes a Mississippi school and colony for the feeble-minded and provides a plan for a chancery court to commit feeble-minded individuals to this institution. The bill carries an appropriation of \$200,000.—In two orphanages in Mississippi with a population of 2,080, forty-one children were found so defective mentally that they could never be made self-supporting citizens.

NEW YORK

Influenza.—Madison Barracks at Sacketts Harbor has been quarantined against influenza. The measure is precautionary, as only one case of the disease has thus far developed.—Influenza has broken out among the inmates of Sing Sing prison, and so many are ill that the prison schoolrooms have been turned into an auxiliary hospital to care for the patients. The prison is in need of nurses and special facilities.

New York City

Fire in Hospital.—A fire recently occurred in the administrative part of the Lenox Hill Hospital, but was promptly controlled. The loss is estimated at \$5,000.

Influenza on Liner.—The Cunard Line S. S. *Kaiserin Augusta Victoria*, sailing from New York, January 17, arrived in Plymouth, England, with sixty cases of influenza aboard and reported one death from the disease during the passage.

Red Cross Starts Health Service.—The New York County chapter of the American Red Cross has organized within the chapter a new department of health service the object of which is to strengthen existing public health agencies. George R. Bedinger is acting director of the new department.

Personal.—Dr. Jacques Loeb of the Rockefeller Institute for Medical Research has been elected president of the American Society of Naturalists.—Dr. Abraham Jablons has been appointed medical inspector in the bureau of hygiene of the department of health.—Dr. James MacFarlane Winfield, for many years professor of dermatology in the Long Island College Hospital, has resigned.—Dr. Rudolph Matas, professor of general and clinical surgery at Tulane University, New Orleans, was elected an honorary member of the New York Academy of Medicine at the annual meeting, January 15.—Dr. Sigmund Pollitzer has been elected a corresponding member of the French Society for Dermatology and Syphilis.—Dr. William Golden Mortimer has been elected director of the ophthalmologic department of the new throat, nose and lung hospital, and designated special surgeon to the throat, nose and ear department.

The Influenza Epidemic.—January 30, the health department reported 5,532 new cases of influenza and 831 cases of pneumonia, an increase of 831 cases of influenza and a slight increase in the number of cases of pneumonia over the preceding day. From the onset of the epidemic there have been recorded 30,000 cases of influenza and 6,031 cases of pneumonia, with 545 deaths from influenza and 1,696 from pneumonia. It is believed that the epidemic has not yet reached the peak. The disease is, however, manifestly milder than in 1918. To meet the acute shortage of nurses, the health department is opening an emergency training school for nurses at 505 Pearl Street, where no charge will be made for the training. The police department, cooperating with the sanitary squad of the health department, has placed officers in the elevated and subway stations to serve summonses on those who spit or carry lighted cigars in forbidden places.

Death Rate for 1919.—The death rate of New York City last year reached the lowest level ever recorded since the establishment of accurate vital statistics fifty years ago. The rate for the year was 12.39 per thousand as compared to 16.71 in 1918, and 13.94 for the five year period 1913 to 1917, inclusive. Generally speaking, where two persons died fifty years ago out of every thousand population, only one

died during 1919. This tremendous reduction in the death rate is the direct result of preventive measures on the part of the sanitary officials. The diseases in which the rate was lowered were typhoid, malaria, smallpox, measles, scarlet fever, whooping cough, diphtheria, tuberculosis and diarrheal diseases of children. The lowest annual infant mortality rate recorded in the history of the city of New York was in 1917, when the rate was 88.8 per thousand children born. The second lowest rate was in 1918, when, with a birth registration of 138,046, there were 12,657 infant deaths and an infant mortality rate of 91.7 per thousand children born. For the first forty-five weeks of 1919, the infant mortality rate, based on a thousand births, was 86 as against 91 for the corresponding period in 1918, and 89 in 1917.

NORTH CAROLINA

New Officers.—At the annual meeting of the Wake County Medical Society held in Raleigh, January 8, Dr. Clarence A. Shore, Raleigh, was elected president; Dr. James M. Harper, vice president, and Dr. William C. Horton, Raleigh, secretary-treasurer.

Hospital Items.—The North Carolina General Hospital has been incorporated and has let the contract for a \$40,000 five-story building to be located at Wilson. The new Carpenter-Davis Hospital, Statesville, was opened, January 9, by Drs. Forest A. Carpenter and James W. Davis, Statesville.

County Health Work.—At present twenty-two counties, which include 38 per cent. of the population of the state, have provided for whole-time health officers. Of these fourteen have county health departments conducted in cooperation with the state board of health, and in addition to these, Bertie, Vance, Beaufort, Union and Harnett counties have made appropriations and asked for cooperation from the state board of health. There are also eight counties with whole-time health officers or health departments conducted independently and without cooperation or coordination with the state board of health.

OHIO

County Health Board Activities.—Seventeen of the eighty-eight counties of the state have already filed health budgets with the state department of health. Eight of these districts have reported the appointment of health commissioners and have the new health machinery in operation under the Griswold laws.

Hospital Items.—The erection of a new state hospital for the insane to be located on a farm of 1,000 acres in northeast Ohio, and the sale of the present Cleveland State Hospital, have been recommended by the state board of administration to the governor. Bids for the erection of a municipal hospital in Youngstown have been received by the municipal hospital commission.

Personal.—Dr. Roy L. Pierce, Mount Gilead, has been selected health commissioner of Morrow County. Dr. Fred W. Upson, Conneaut, was operated on for intestinal obstruction at Mount Sinai Hospital, Cleveland, January 17. Dr. John A. Burnett, Hamilton, has been appointed physician for the public schools of Hamilton. Dr. J. Milton O'Neal, New Concord, has been elected health commissioner for Muskingum County.

Summer Course in Medicine.—The school of medicine of Western Reserve University has announced that it will institute for graduates a summer course in medicine. A two months' course will be given in medicine and surgery. The facilities of the medical school, of Lakeside, St. Vincent's, City and Mount Sinai hospitals will be utilized, the latter by special arrangement. The courses have been planned to occupy all of the time of those in attendance, and will be largely clinical in character.

Emerson Addresses Academy.—Dr. Haven Emerson, New York City, who is conducting a survey of hospital facilities in Cleveland for the hospital council, delivered an address at the meeting of the Cleveland Academy of Medicine, January 16, on "The Cleveland Hospital and Health Survey—Its Object and Scope." The report of the special committee recommending the employment of a full-time executive secretary for the academy with an increase in the scope of activities of the organization was presented by Dr. George E. Follansbee, Cleveland.

Fighting Trachoma.—By recent action of the general assembly, the state department of health has been provided

with funds to support an extended campaign against trachoma. The work will be done in cooperation with the U. S. Public Health Service and local health authorities. The tentative program calls for a series of intensive campaigns in individual counties, rather than for a general effort in all sections at once. Clinics will be established, schoolchildren will be examined and treated if necessary and educational measures will be undertaken.

Cincinnati

List Goes to Minneapolis.—Dr. Walter E. List, assistant superintendent of the Cincinnati General Hospital resigned, December 22, to accept the superintendency of Minneapolis City hospitals. He left for his new position, January 15.

New Officers.—At the annual meeting of the Cincinnati Academy of Medicine, January 5, the following officers were elected: president, Dr. H. Kennon Dunham; vice presidents, Dr. Arthur L. Knight and Clement C. Fihe; secretary, Dr. Otto J. Seibert; treasurer, Dr. Alex G. Drury.

Provision for Medical Journal.—Provision for the establishment of a journal for the medical department of the University of Cincinnati was made by the will of Dr. Christian R. Holmes, which sets aside a fund of \$25,000 for this purpose, payable to the trustees of the university in annual instalments of \$5,000. If the publication of the journal is not commenced within a year of Dr. Holmes' death the bequest is void.

Fund for Medical Research.—As a permanent memorial of Dr. Christian R. Holmes, his friends have inaugurated plans to raise a fund of \$1,000,000 for medical research, the endowment to be known as the Christian R. Holmes Medical Research Fund. The Carnegie Corporation has made a gift of \$250,000 to the medical college of the University of Cincinnati, as a tribute to Dr. Holmes' services to humanity and to endow a chair in his memory.

PENNSYLVANIA

Personal.—Dr. Robert B. Mackey, Waverly, has been commissioned major, M. C., Pa. N. G., and assigned to duty with the Thirtieth Infantry. The commission of Capt. Robert F. Trainer, M. C., Pa. N. G., Williamsport, expired, Dec. 19, 1919.

Public Health Nurses Organize.—At a meeting of the public health nurses at the state dispensary, Williamsport, January 5, organization was effected of the Public Health Nursing Association, whose membership includes the state nurses located in the city, the nurses from the various industrial plants, the school nurses and others.

Influenza in the State.—Director Charles W. Sheldon, Tioga, district supervisor and medical director of the state department of health, reports a total of 1,500 cases in Williamsport and outlying districts. The death rate has been small, but an appeal for nurses has been sent to Harrisburg. In Scranton, thirty cases of influenza and one death were reported, January 29. More than sixty cases of influenza, with several deaths, have been reported at York.

Society Meeting.—The ninety-fifth annual meeting of the Franklin County Medical Society was held in Chambersburg, January 20, and the following officers were elected: president, Dr. Joseph P. Maclay, Chambersburg; vice presidents, Drs. Samuel B. Thomas, Waynesboro, and William E. Holland, Fayetteville; secretary, Dr. John J. Coffman, Scotland (reelected); assistant secretary, Dr. Samuel D. Shull, Chambersburg, and treasurer, Dr. Frank N. Emmert, Chambersburg.

Philadelphia

Personal.—Dr. J. Blair Spencer, lieutenant in the naval reserve force during the war, has been appointed chief physician in the bureau of charities and correction in the department of welfare. Dr. Henry N. Speer has been commissioned first lieutenant, M. C., Pennsylvania Reserve Militia, and assigned to duty with the First Infantry.

Health Clown Lectures.—Cho-Cho, the health clown who entertained Philadelphia schoolchildren several months ago with health talks, gave four lectures in the city, January 28 and 29, under the auspices of the Woman's Medical College of Pennsylvania. These were arranged to give the students and nurses an opportunity to study his methods.

Influenza.—While there is no fear of a grip epidemic, every precaution is being taken. One hundred and six new cases of mild influenza were reported, January 29. Since

the beginning of the year there have been only twenty-three deaths from pneumonia. Of the forty patients at the Philadelphia Hospital, many were discharged as convalescents, January 29, and only four new cases brought in. Of the deaths since the first of the year, two occurred during the week ending January 2; two in the week ending January 9; five in the week ending January 16; three in the week ending January 23, and eleven in the week ending January 30. There has been a slight drop in the number of daily cases reported.

RHODE ISLAND

Health Officer Reelected.—Dr. Charles V. Chapin, who has served the city of Providence for thirty-six years has been reelected superintendent of health for a three-year term.

New Officers.—At the annual meeting of the Kent County Medical Society, December 4, Dr. Frank B. Smith, Washington, was elected president and treasurer; Dr. Benjamin F. Tefft, Jr., Anthony, vice president, and Dr. J. Fulgence Archambault, Arctic, secretary.

Society Honors Associate.—The Kent County Medical Society gave a reception and banquet, December 4, in honor of Lieut. Philip C. Means, Apponaug, who recently was discharged from the military service, and is about to move to California. Dr. H. Barton Bryer, Natick, presided as toastmaster.

Physician Surrenders for Jail Term.—Dr. Frederick O. Balcom, Providence, convicted in the United States District Court in November, 1918, of violation of the espionage act, surrendered, December 2, to the United States marshal and was taken to the Providence County Jail to serve a sentence of one year. It is said the violation consisted in speaking privately against the sale of Liberty Bonds and the enforcement of the draft act.

Low Death Rate.—Figures recently published show that the death rate in Providence in 1919 was 13.22 per thousand. Notwithstanding the fact that there were in the early part of the year, 230 deaths from influenza and quite an excess from pneumonia, the death rate for the year was considerably lower than that of any year since registration began in 1856. Nearly every cause except diphtheria, cancer and Bright's disease showed a decrease. The death rate from pulmonary tuberculosis was the lowest ever recorded and that for pneumonia the lowest since 1877. The deaths from summer diarrhea and other causes of infant mortality were far lower than ever before. Typhoid fever caused only nine deaths.

WISCONSIN

Personal.—Dr. Otto A. Fiedler, Sheboygan, has been reappointed a member of the state board of health.—Dr. John B. MacLaren, Appleton, has been appointed a member of the federal committee on sanitation of the Wisconsin Industrial Commission.

State Health Board Meeting.—At the annual meeting of the state board of health in Madison, January 20, the following officers were reelected: president, Dr. William F. Whyte, Madison; secretary and state health officer, Dr. Cornelius A. Harper, Madison; assistant secretary, L. W. Hutchcroft, Madison; and the appointment of Dr. Frank F. Bowman, Madison, as deputy state health officer for the Southern Wisconsin District was confirmed.

New Officers.—At the annual meeting of the Brown-Kewaunee County Medical Society held at Green Bay, January 7, Dr. William E. Fairfield was elected president. Dr. Henry P. Rhode, vice president, and Dr. Arthur J. McCarey, secretary-treasurer, all of Green Bay.—Milwaukee County Medical Society at its annual meeting, January 13, elected the following officers: president, Dr. Alfred W. Gray, Milwaukee; vice presidents, Drs. Wilbur L. LeCron, Milwaukee, and Charles A. Fidler; secretary, Dr. Oscar S. Lotz, Milwaukee, and treasurer, Dr. Joseph P. McMahon, Milwaukee.

Physician Not Fined.—Dr. Francis W. Starr, Stanley, who was chronicled in THE JOURNAL, January 3, as having been fined \$25 for having broken the rules of the state board of health regarding public funerals over remains of persons dying from contagious disease, writes that he was not fined; that an overzealous district health officer had him arrested on a technicality; that he pleaded guilty and the court did not see fit to fine him; furthermore, that the court was so thoroughly convinced that the arrest was unwarranted that it did not impose court costs; that the district attorney asked

that no costs be assessed on his account, and finally that the county sheriff put in no claim for costs.

CANADA

Personal.—Dr. Frederick E. Watts, Toronto, has returned from overseas and resumed the practice of surgery.—Col. David W. McPherson, Toronto, commanding the Ontario Military Hospital, England, has returned to Toronto.

University News.—The county of Middlesex, in which is situated the city of London, is being asked by the Western University, London, Ont., for financial assistance. Somewhere between \$60,000 and \$80,000 is expected and will be applied to either the arts building or for dormitories.

Hospital News.—The city hospital governors of Hamilton and St. Catharines, Ont., will ask the Ontario government to increase their governmental grant from 7 cents a day for children and 30 cents a day for adults to 30 and 75 cents, respectively. It costs on an average \$2.87 a day per patient to run these hospitals.—Representatives of all hospitals in Ontario receiving government grants met in Toronto the past week, the object being to seek increased grants from municipalities and the government. They will endeavor to secure a sliding scale of grants which will go up or down as the cost of maintenance rises or falls.

GENERAL

New Academy Officers.—At the annual meeting of the Sioux Valley Eye and Ear Academy held in Sioux City, January 20, the following officers were elected: president, Dr. James E. Reeder, Sioux City, Iowa; vice president, Dr. Frank I. Putman, Sioux Falls, S. D., and secretary-treasurer, Dr. Lorenzo N. Grosvenor, Huron, S. D.

Mortality in 1918.—According to the mortality statistics of the census bureau for 1918, issued February 2, the death rate in the United States for that year was the highest on record, showing 1,471,367 deaths for the year, representing a rate of 18 per thousand population in the registration area with an estimated population of 81,868,104. Of the total deaths, 477,467, or more than 32 per cent., were due to influenza and pneumonia.

Red Cross Bureau of Disaster Preparedness.—This bureau was created by the American Red Cross for the purpose of mobilizing the resources of community, state and nation, for immediate relief in the event of disaster. The record of one disaster a month for every month of fourteen years makes preparedness an imperative need. A loose leaf disaster relief guide book is being issued, and plans have been outlined for instituting a vigorous campaign for disaster preparedness in every locality, so that when an emergency comes the Red Cross will be ready on the instant to meet the situation.

American Red Cross Special Reserve Fund.—At a meeting, held Nov. 19, 1919, the executive committee of the American Red Cross voted to set apart from the securities donated to the Red Cross war fund a sum representing \$10,000,000 in market value of those securities on this date as a special reserve, subject to such reinvestment as may be determined by the executive committee from time to time, and the income from which shall be available for the general purposes of the Red Cross. The principal sum is to be maintained always up to the full amount of \$10,000,000, and it is not to be drawn on except to meet an emergency for which the other resources of the Red Cross at the time are inadequate.

Personal.—It is reported that Dr. William H. Kingston, Hogsburg, N. Y., and Joseph N. Meddill, Jaroso, Colo., who have been working with the American Red Cross in Siberia, were captured by bolsheviks, January 25.—Drs. George C. Shattuck, Boston, chief medical secretary and Thomas R. Brown, Baltimore, chief of medical information and medical publication of the League of Red Cross Societies, have gone to Geneva.—Dr. Edouard Rist, physician in chief of the department of tuberculosis at the Laennec Hospital, Paris, has been appointed chief of the division of tuberculosis of the League of Red Cross Societies.—Lieut.-Com. Joel T. Boone, M. C., U. S. Navy, has been assigned to duty as director of the bureau of naval affairs at headquarters of the American Red Cross.

Fraternity Election.—At the annual convention of the Phi Delta Epsilon fraternity which has twenty-five chapters among class "A" medical schools, held in Philadelphia, the following officers were elected: grand consul, Dr. Nathan

Blumberg, Philadelphia; deputy grand consul, Dr. David W. Kramer, Philadelphia; vice grand consuls, Drs. Leo S. Schwartz, New York City, Frank M. Chesner, Philadelphia, Samuel Nadel, Boston, Jacob Greenberg, Baltimore, Louis Bothman, Chicago, and George Piness, Los Angeles; grand chancellor, Dr. Benjamin E. Spiegel, New York City; grand scribe, Dr. Monroe E. Greenberger, New York City; grand historian, Dr. Murray B. Gordon, New York City; grand marshal, Dr. August C. Schwenk, New York City, and editor, Dr. Aaron Brown, New York City.

Bequests and Donations.—The following bequests and donations have recently been announced:

Methodist Episcopal Hospital, Philadelphia, \$25,000, the income of which is to be used in the establishment and maintenance of five free beds by the will of Thomas Bradley.

Georgia Medical Society \$1,000 for the establishment of the William Mears Library Fund in memory of an ancestor who came from England to Savannah in 1735, by the will of Dr. J. Ewing Mears, Philadelphia.

Bryn Mawr, Pa., Hospital, \$50,000, by the will of Mrs. A. J. Cassatt. Home for Incurables, Philadelphia, \$10,000; Methodist Hospital, Philadelphia, \$5,000; Frankford, Pa., Hospital, \$500, by the will of Marian L. Elliot.

Episcopal Hospital, Philadelphia, \$1,000 by the will of Florence W. Holbrook.

Hospital for Crippled Children, Baltimore, \$1,000 by the will of Mrs. Joseph L. Johnston.

Reinstatement of War Risk Insurance.—Announcement is made by Director R. G. Cholmeley-Jones of the Bureau of War Risk Insurance that the provisions still apply for reinstatement of lapsed or canceled insurance, within eighteen months from date of discharge, on payment of only two months' premiums provided the insured is in as good health as at the date of discharge or expiration of the grace period, whichever is the later date, and so states in his application. The provision that discharged service men are permitted to reinstate at any time within three calendar months following the month of discharge by merely paying the two months' premiums, without making a formal application or a statement as to health is also still in force. The provisions for reinstatement do not protect a man until he actually reinstates. If he waits, he may not be in as good health as he was at the time of discharge and consequently may not be able to secure reinstatement.

Appropriation for National Research Council.—The Carnegie Corporation of New York has announced its purpose of giving \$5,000,000 for the use of the National Academy of Science, and the National Research Council. It is understood that a portion of the money will be used to erect in Washington a suitable home for the two beneficiary organizations, and that the remainder will be placed in the hands of the academy to be used as a permanent endowment for the council. The council was organized in 1916, as a measure of national preparedness and during the war its efforts were confined chiefly to assist the government in the solution of pressing war-time problems which involved scientific investigations. Since the war it has attempted to stimulate and promote scientific research in agriculture, medicine, industry and in every field of pure science. The council is based on forty of the great scientific and engineering societies of the country which elect delegates to its constituent divisions.

Appropriation to Public Health Service.—Congress has met the urgent need for additional hospital accommodation and equipment in the Public Health Service by appropriating \$4,000,000 available for immediate use. These funds will be used in hospitals occupied by war risk insurance patients. An additional \$500,000 is appropriated for expenditure at government hospitals located as follows:

Deming, New Mexico	\$20 000
Alexandria, La.	25,000
Houston, Texas	10,000
Perryville, Maryland	75,000
Greenville, S. C.	75,000
Cape May, N. J.	10,000
Hoboken, N. J.	10,000
Danville, N. Y.	10,000
St. Louis, Mo.	5,000
New Haven, Conn.	25,000
West Roxbury, Mass.	50,000
Helena, Mont.	100,000
Boise, Idaho	75,000
East Norfolk, Mass.	10,000

The sum of \$15,000 is provided for the propagation and sale of viruses, toxins and analogous products. This same appropriation bill forbids the Public Health Service to use any of its funds for advertising in newspapers or magazines hereafter.

FOREIGN

New Year Honors.—The list of British new year honors includes the elevation of Sir Bertrand Dawson, physician-in-ordinary to the king and dean of the medical faculty of the University of London, to a peerage.

Defective Children in England.—The chief medical officer of the board of education reported that of 533,400 children outside of London physically examined in 1918, 259,000, or 48.5 per cent., were found to be defective.

Physicians in Egypt Raise Their Fees.—The *Presse médicale d'Egypte* is a fortnightly journal published at Cairo, now in its eleventh year. A recent issue states that the physicians of Cairo recently voted at a meeting, called by Dr. Comanchos Pacha, to advance the fees to twice that of the figure before the war. About sixty physicians attended, and the resolution stated that the time had come for physicians in Cairo to follow the example in this respect of their confrères in Alexandria and in Europe.

Italian Orthopedics Congress.—Our Italian exchanges mention that the X Congresso di Ortopedia was held recently at the Rizzoli Orthopedic Institute at Bologna, and great interest was aroused by Albee's description of his bone-grafting operation in Pott's disease, with demonstration. The main themes appointed for discussion were prostheses and treatment of pseudarthrosis, introduced by Dalla Vedova and Palagi. Prof. V. Putti presided at the meeting, and Francioni delivered an address on the morphologic evolution of the human organism during the first years of life.

Health Congress in Brussels.—The Royal Institute of Public Health announces that it will hold a congress in Brussels from May 20 to 24, inclusive, under the patronage of the king of the Belgians. The council has invited delegates from the British universities, municipal corporations, and other bodies interested in public health, and has taken steps through the British division of the American University Union in Europe to extend a like invitation to the universities, municipal corporations and public health associations of the United States.

Typhus Fever.—To aid in combating the serious outbreak of typhus fever in Esthonia, where 15,000 cases have been reported, Col. Edward J. Ryan of the American Red Cross has obtained the services of twenty physicians of the French health service for a period of two months.—Typhus fever is reported to be making increased ravages in eastern Galicia, where it is said there are more than 100,000 cases of the disease, with a mortality of about 10 per cent.—The Swedish consul at Reval reports that there are 4,600 cases of typhus fever among Russian soldiers at Narva, 3,500 cases at Wesenberg, and 2,000 cases at Ziegelkoppel.

Medical Congress in Palestine.—The *Nederlandsch Tijdschrift* relates that the first large conference of the Jewish physicians in Palestine was held recently at Jaffa. Out of the seventy Jewish physicians in the country, forty were in attendance. The medical problems of Palestine were the main topics for discussion. The meeting was presided over by Dr. Mase of Jerusalem, and Dr. Puchowsky delivered the opening address. A resolution was adopted urging the necessity for nationalization of the medical service, and a committee of five was appointed, including Drs. Beham, Goldberg and Norman, to collect data and outline plans. A greeting was sent by telegram to Dr. Max Nordau, who was elected an honorary member of the Palestine Medical Association.

Near East Relief.—The Near East Relief is a body incorporated by act of Congress to provide relief and to assist in the repatriation, rehabilitation and reestablishment of suffering and dependent people of the Near East and vicinity, to provide for the care of orphans and widows, and to promote the social, economic and industrial welfare of those who have been rendered destitute or dependent by the vicissitudes of war. At present 168 orphanages are being operated in Armenia by this organization, and there are more than 82,000 workers in the industrial establishment. About 500 workers are now in the field, including 26 physicians, 76 nurses, 7 mechanics, 15 industrial experts, 16 agriculturists, 197 relief workers, 19 teachers, 34 secretaries, 7 engineers and 45 army officers. The principal centers of activities are Aintab, Adana, Konia, Smyrna, Marsivan, and Samaun, in Asia Minor; Aleppo and Beirut in Syria; Jerusalem in Palestine; Bagdad and Moussoul in Mesopotamia; Erivan, Batum, Tiflis, Alexandropol and Baku in the Caucasus; Tabriz and Teheran in Persia, and Constantinople in Turkey.

Government Services

Disease Conditions in the Army

During the week ending January 23, influenza and pneumonia prevailed to some extent in nearly all the camps and stations in the United States. In most of the camps the epidemic had reached its peak and was beginning to decline. Among the American forces in Germany, influenza and measles continue to be reported, but there also the number of deaths from pneumonia shows a marked decrease. Conditions in the American forces in Siberia are reported excellent.

Increased Pay Under New Army Bill

Medical officers of the Army, Navy and Public Health Service are given a 10 per cent. annual increase in the Army-Navy Pay Bill which is being urged for passage in the Senate by Chairman Wadsworth of the Senate Committee on Military Affairs. The bill gives a 20 per cent. increase to members of the female Nurse Corps of the Army and Navy. The bill also contains a special provision whereby the federal government furnishes transportation for the wife, children and dependents of officers when ordered to make a permanent change of station. Heretofore it has always been the custom to furnish transportation to officers and enlisted men but not to their families.

Notification of Epitheliomatous and Chrome Ulceration

A physician attending a patient whom he believes to be suffering from poisoning by lead, phosphorus, arsenic or mercury, or anthrax, or toxic jaundice, contracted in a factory or workshop, is already required to notify the case to the chief inspector of factories. An order has now been made extending the obligation to (a) epitheliomatous ulceration due to tar, pitch, bitumen, crude oil, paraffin, or any compound, product or residue of these substances, and to (b) chrome ulceration, due to chromic acid or ammonium, sodium or potassium bichromate or any preparation of these substances, occurring in a factory or workshop. The following explanatory statement is added by the factory department of the Home Office (the department of the government which deals with home affairs):

1. Epitheliomatous Ulceration: In general ulceration of the skin, this term is used to define a raw surface forming on the skin, which in industrial employment is not infrequently set up by the substances handled. Under appropriate treatment, at no matter what age, such ulceration usually heals quickly and, should it recur, will again heal with rest and treatment. In the case of those handling the substances named, however, especially when over 35 years of age and having worked for about ten years or more in operations exposing them to dust or liquids, the ulceration may not heal but spread over the skin and extend downward. This form of ulceration occurs with relative frequency on the scrotum. It is then to be regarded as epitheliomatous and to be notified. The only treatment is operation, which should be performed as early as possible.

2. Chrome Ulceration: If chrome compounds and their solutions remain in contact with the broken skin (and sometimes, with a very sensitive skin, in the absence of an obvious broken surface), they give rise to either a general eczematous ulceration or a circumscribed ulcer known as a "chrome hole." Both these conditions when definitely ulcerative are reportable. Recurring attacks of epitheliomatous and of chrome ulceration should be reported when they appear in a fresh place.

Conflict Between the Friendly Societies and the British Medical Association in Australia

A struggle has been going on for many years between the friendly societies of Victoria and the physicians. The conditions under which lodge physicians worked were considered unsatisfactory, particularly as to remuneration, which aver-

aged yearly per member (including wife and children) about \$3.25, and sometimes was as low as \$1.50. There was no income limit, and some of the richest men availed themselves of this low rate. To ameliorate these conditions, the profession organized until more than 90 per cent. became members of the Victoria branch of the British Medical Association. In December, 1913, a conference was held between the physicians and lodge representatives, and in July, 1914, another conference at which a subcommittee was chosen; but war broke out, and the matter was postponed. In March, 1917, the matter was revived, and various conferences were held without reaching any agreement. The lodge physicians, therefore, to the number of 98 per cent., tendered resignations taking effect from Jan. 31, 1918. During this year various efforts were made by the state government to effect a settlement on behalf of the Friendly Societies Association by proposals of arbitration. But the council of the British Medical Association contended that the rate to which they agreed—\$5 in the town and \$6.25 in the country—was a concession to the less remunerated classes, and that the physicians themselves were the only persons to decide what the concession should be and to whom it should be granted. Consequently the council refused all proposals to arbitrate, in spite of threats of the state parliament. The parliament appointed a royal commissioner to investigate the dispute. In his finding he granted virtually all that the physicians had asked. Both sides offered to accept this finding, but the council insisted that the medical institutes, which had been established since the resignations had been submitted in order to supply medical attendance, should be abolished. This the friendly societies refused on the grounds that it would be an interference with their legal rights to establish institutes and that their members are bound by legal agreement to support the institutes for three years. Thus a deadlock was reached. The medical attendance furnished by the institutes does not appear to be satisfactory to the societies. Nineteen have recently agreed to turn down the institutes and to accept only British Medical Association physicians for their medical officers. The societies have requested parliament to appoint whole-time state health officers to whose duties shall be added attendance on friendly society members. They have also resolved to send a representative to England to secure 100 physicians to act as medical officers with a tempting offer of \$5,000 a year, with extras for midwifery and surgery. The council has written to the *British Medical Journal* asking it to assist them in preventing an influx of physicians from England. The *Journal* has responded by an article to this effect.

PARIS

Dec. 31, 1919.

Personal

The Académie de médecine has recently reorganized its bureau. Following the usual custom, Professor Laveran, formerly vice president, has assumed the duties of president for the year 1920. Dr. L. G. Richelot, hospital surgeon and agrégé professor of the Faculté de médecine of Paris, was chosen vice president for the year 1920, and Dr. Achard, also of the Faculté de médecine of Paris, was elected secretary for the year.

Dr. F. Lejars, professor of clinical surgery of the Faculté de médecine of Paris, has been elected president of the Société de chirurgie for the year 1920.

The Next International Conference of the Red Cross

The International Committee of the Red Cross has settled on Sept. 1, 1920, as the date for opening the tenth international conference of the Red Cross, which will hold its meetings in Geneva. It is planned to have a ten day conference. Among the subjects that will be brought up for discussion are: the experience gained during the late war; the mutual relationship of the Red Cross societies, and the extended development of the Red Cross societies in their peace and war activities. An executive committee has been put in charge of the preparations for the conference.

The Antagonism Between Epinephrin and Quinin

Drs. A. Clerc and G. Pezzi recently communicated to the Académie des sciences the results of their researches, which go to prove that there is an antagonism between the action of quinin and that of epinephrin, but that nevertheless there is no absolute opposition in the different modes of action of the two substances. There is complete antagonism in the cells of the hulbar center of the pneumogastric nerve, for epinephrin stimulates and quinin paralyzes this nerve. There is also antagonism with respect to cardiac action, epinephrin

having a stimulating and accelerative effect and quinin acting as an inhibitor and depressant. There is even antagonism in regard to arterial pressure: epinephrin produces hypertension and quinin hypotension. But epinephrin causes hypertension by a cardiac and vascular action combined, whereas quinin produces hypotension by overcoming the vasoconstrictive action common to the two substances, although in a different degree.

Even allowing for the vasoconstrictive mode of action which is common to the two substances, the antagonism between them is nevertheless noteworthy. While epinephrin acts as a stimulant of the sympathetic nervous system, quinin must be accorded a sedative action, which makes possible new therapeutic applications.

The Reorganized Strasbourg Faculty of Medicine

In a previous letter (THE JOURNAL, Nov. 8, 1919, p. 1456), I gave some general information concerning the University of Strasbourg. I can now add a list of the names of those who have been appointed on the new medical faculty:

Professor of embryology, Dr. Ancel (of the Faculté de médecine de Nancy); professor of histology, Dr. Bouin (of the Faculté de médecine de Nancy); professor of pathologic anatomy, Dr. Masson (of the Institut Pasteur of Paris); professor of biophysics, Dr. G. Weiss (of the Faculté de médecine de Paris); professor of physiologic chemistry, Dr. Nicloux (of the Faculté de médecine de Paris); professor of pharmacology and experimental medicine, Dr. Ambard (of the Faculté de médecine de Paris); professor of clinical surgery, Dr. Sencert (of the Faculté de médecine de Nancy); professor of clinical dermatology, Dr. Pautrier; professor of neurology, Dr. Barré; professor of otorhinolaryngology, Dr. Baldenweck; professor of clinical ophthalmology, Dr. Duverger (of the Ecole de médecine of Limoges); professor of legal medicine, Dr. Chavigny (of the Ecole d'application de médecine et de pharmacie militaires du Val-de-Grâce); professor of anatomy, Dr. Forster (formerly privat-docent of the Faculté de médecine of Strasbourg); professor of clinical medicine, Dr. L. Bard (of the Faculté de médecine of Geneva); professor of clinical medicine, Dr. Blum (formerly privat-docent of the Faculté de médecine of Strasbourg); professor of clinical surgery, Dr. Stolz (formerly privat-docent of the Faculté de médecine of Strasbourg); professor of clinical psychiatry, Dr. Piersdorff (of the Faculté de médecine of Strasbourg); professor of gynecology and obstetrics, Dr. Schiekle (formerly privat-docent of the Faculté de médecine of Strasbourg); professor of hygiene and bacteriology, Dr. Borrel (of the Institut Pasteur of Paris).

Apartments for Large Families

The municipal council of Paris has recently asked the administration to take up with the national government and with the Sociétés d'habitations à bon marché the question of according certain special privileges to families having more than four children; namely, the right of priority in the matter of securing low-priced apartments, and a reduction in rent in proportion to the number of children, it being understood that the national government, the department or the commune is to bear the burden of such reduction.

LIMA

Dec. 31, 1919.

Sanitary Victory

The yellow fever epidemic which began about the middle of this year, in the northern part of Peru, has just been officially declared as having come to an end. An active sanitary campaign directed at first by Mr. H. Hanson and afterward by Drs. Gastiaturú, Quirós and Almenara deserves the credit for its eradication. Some interesting studies have been made about *Leptospira icteroides*, which may throw new light on the etiology of this disease. Cultures of *Leptospira icteroides* have been made at the hygienic laboratory of Lima. The number of cases during the epidemic amounted to more than 200, with a mortality rate of 40 per cent.

Infant Welfare

There has been organized during this month the Sociedad protectora de la Infancia, under the presidency of Mr. Miguel Echenique, a well-known philanthropist, and Dr. Rodolfo Neuhaus, a pediatrician. In order to secure public support there was organized a "child and flower day" which produced several thousand soles (a sol is about half a dollar). This will be employed to install the association headquarters in addition to an office of public assistance for children.

People interested in this society can obtain further data from the secretary, Lima, Peru, Apartado 987.

University Changes

During the whole second semester of this year there has taken place a true university revolution caused by the desire of the students to introduce reforms in the methods of teaching. This conflict has become so serious in the School of Medicine that it was necessary to discontinue the classes during the present year with the natural loss to those coming up for examination. As a result of the support rendered by the government to the justified demands of the students, there have been changes affecting about one third of the personnel. Among the new professors in the School of Medicine are included Drs. Anibal Corvetto, Edmundo Escomel, Constantino Carvallo, Jr., Carlos Monge, Carlos Morales Macedo, Enrique León García, and Carlos Enrique Paz Soldán. In addition, the students will be represented directly in the directing council of the university, having elected as their representatives Drs. Enrique Paz Soldán and José Antonio Encinas.

Important Visit

Active preparations are being made to welcome Dr. W. J. Mayo and his associates. The Society of Surgery and the Faculty of Medicine have appointed commissions to receive them and attend to their comfort. This visit will be very important from the standpoint of better scientific relations between North and South America.

LIÈGE

DEC. 15, 1919.

The Technic of Appendectomy

Referring to the various objections that can be made to the numerous incisions proposed for appendectomy, and especially to the Jalaguier and the Lennander incision, R. Danis described at the recent meeting of the Société belge de chirurgie certain recent modifications of the McBurney incision, with a view to securing more solid and less visible cicatrization, and, at the same time, more constantly direct access to the appendix, no matter what its position may be. He discussed in detail the question of the direction and the localization of the skin incision.

The end of the appendix is located on a line drawn from the right iliac spine to the left pubic spine, at a point about 3 cm. external to the former. An incision made at the level of this line gives regular access to the cecum. Whether the meso-appendix is long or short, the cecum can easily be made to appear in the wound, and the appendix will always be in the field if its position is normal (laterocecal or retrocecal), the base appearing first, at the moment the head of the cecum is drawn up through the wound.

The author made the following remarks in connection with the location of the incision: The vertical incision comes in contact with a great many nerve fibers, for example, the ends of the lower dorsal nerves, which are directed obliquely downward and inward, and thus produces a large area of anesthesia between the cicatrix and the median line, which lasts for several months and causes the patient great discomfort. The more obliquely the incision is made, the less extended the area of anesthesia becomes. Danis gave an illustration of the good effects of rotating the incision by referring to a cardboard, which, when held perpendicularly to the rays of light, casts a broad shadow, but as it is held less and less perpendicularly the shadow grows smaller and smaller until it becomes a mere line. The suppression of the anesthetic shadow, that is to say, the gradual decrease of the zone of anesthesia, is the indication for the direction of the incision. In short, the author advises a very oblique incision, inclined toward the horizontal, and located much lower than the McBurney incision.

The Treatment of Pleural Suppurations

At the same meeting of the Société belge de chirurgie, Janssen reported the good results that he had secured in cases of chronic pleural suppuration by pleurectomy, either with or without thoracotomy. He communicated seven interesting observations, and drew the conclusion that every pleural suppuration of from two to three months' standing requires an operation. Fistulous sequelae, he finds, relate back to various causes: (1) an osteitis of the ribs; (2) the persistence of pleural or pulmonary projectiles, or (3) a pus pouch formed by the pleura itself. In decortication of the lung, the author adopts the technic recommended by

Delorme. He has found it to give perfect end-results. Pulmonary function is restored to almost its normal value. Roentgenography is sometimes serviceable in order to determine before the operation the factors on which a good functional result may be based, namely, as to how far advanced the sclerosis of the lung is; what the thickness of the encapsulating membrane may be, and what the prospects are for an easy removal. The general principles that should guide the operator during the course of intervention are as follows: 1. Any adhesions that bind down the lung, and also the parietal layer of the pleura should be completely removed—a total pleurectomy. 2. Intervention should be by a route that will cause the least possible mutilation: resection of one or two ribs, the trap-door incision as recommended by Delorme. 3. Account should be taken as to whether the pulmonary sclerosis is too far advanced. If such is the case, in addition to the pleurectomy a more or less extended resection of the chest wall should be done. 4. At the end of the operation, the thoracic cavity should be closed by a tight suture, only one drain being left to assure irreversible drainage, that is to say, allowing fluids from within to pass out but preventing the entrance of air into the thoracic cavity. As for postoperative treatment, drainage should not be kept up longer than is necessary, and early active mobilization of the lung should be carried out, the patient being required to take breathing exercises on the second or third day after surgical intervention.

The Venereal Peril

As in all countries that took part in the war, the enormous increase in venereal disease is causing considerable anxiety in Belgium. On account of the spread of syphilis, more especially, the Société médico-chirurgicale du Brabant has addressed a communication to the department of hygiene with a view to realizing three desiderata: 1. An increase in the number of laboratories placed gratuitously at the disposal of the medical corps, for example, the location of a laboratory in each canton for the purpose of carrying on, in aid of physicians, such researches as should prove indispensable for the correct treatment of syphilis. The laboratories might later extend their field of activity so as to include gonorrhea, tuberculosis and all diseases caused by micro-organisms, and thus become valuable scientific centers accessible to all practicing physicians. In this way they would contribute much toward raising the standard of medical efficiency and would inure to the advantage of public health in general. 2. The appointment of syphilologists to be placed at the disposal of the physicians of each canton for such time as should be deemed necessary, with a view to having these specialists examine into and elucidate the difficult cases, in order that the local physicians might gain a thorough knowledge of modern therapeutics as applied to venereal disease. 3. The gratuitous distribution to physicians for the use of patients in straitened circumstances of all specific remedies needed for the treatment of venereal disease on the sole condition that twice a year they should send in a statistical report of the patients treated.

The society also passed a resolution to the effect that a law should be drafted prohibiting the publication in other than scientific journals of advertisements dealing with venereal diseases.

The Etiology of Arthritis

At the meeting of the Société belge de biologie, Cohen introduced an interesting communication on the subject of the pathogenic agent in arthritis. In the blood of a patient afflicted with a very severe type of arthritis to which he succumbed shortly afterward, he found, in 1916, a diplococcus resembling a gonococcus and a meningococcus but differentiating itself from these by the fact that it grew exclusively on a blood medium. In the complement-fixation test the blood serum of this patient was strongly positive for this microbe, and also for the gonococcus and certain meningococci. This microbe has not been found since in the latest researches bearing on the blood of rheumatic patients; but in twenty-eight cases of arthritis presenting no acute or recent gonococcal infection he found that the blood serum of twelve patients was strongly positive for this microbe, the gonococcus and certain meningococci.

Industrial Diseases Among Coal Miners

At a recent meeting of the Académie royale de médecine, Herman presented an important communication on the subject of an industrial disease that it has been decided to call "maladie du brai," or pitch disease. Among workmen engaged

in the manufacture of coal dust briquets, for which pitch is used as a binding material, certain cutaneous and ocular symptoms have been discovered that are sufficiently characteristic to give to the disease a definite industrial stamp. In such factories there is one place that is especially dangerous on account of the air being so heavily laden with dust. That is where the pitch is broken up, pulverized and mixed with the coal dust. In the room in which the malaxation of the "dough" takes place and where the briquets are molded and subsequent operations are performed, the workmen are not exposed to any danger, for here the work is done within closed vessels and with dampened material, so that the dust is thus kept down.

Prophylaxis of the affection must look toward the suppression of the dust, which can be accomplished only by substituting a machine method for the present hand method of breaking up the pitch and transporting it in wheelbarrows to the pulverizer. The best way would be to transfer the contents of the railway car to the mixer, raising as little dust as possible, from which point on the manufacture of coal dust products would be harmless. Keeping down the dust by means of fans and spraying does not seem practicable.

Until a radical solution is found, it behooves the individual workmen to take such precautions as they can: 1. Clothing should be worn that is tight fitting at the neck, the wrists and the ankles. Tight-fitting goggles might well be worn over the eyes, and protecting ointments might be used on the exposed portions of the body. 2. Daily shower baths and careful attention paid to the skin would help. 3. Workmen who have already been affected should be temporarily removed from the dust zone. 4. The work day, eight hours at the most, should be divided into two parts, with long enough time between to allow the workmen plenty of time to wash up thoroughly and get rested after their trying and wearisome toil.

Bayet, also, has been making a study of arsenical poisoning in coal miners. He finds that this is much more widespread than is commonly supposed. He has shown that this form of poisoning menaces and afflicts thousands of workmen that were not thought of as being exposed. This finding is all the more significant since the arsenic that is the cause of these accidents comes from a substance that is universally used—perhaps the most universally used of any substance in industrial labor—namely, coal. The workmen most exposed are those who handle tar and its derivatives, distillers of tar, tarrers of bolts and crossbars, workmen who manufacture tarred paper, lamp black, crayons and various composites; those who handle oils and greases, crude paraffin, asphalt and bitumen; those employed in coke furnaces and in gas plants, and, we may probably add, workmen engaged in the manufacture of anilin dyes. In this connection, we may take a retrospective look and recall the cancer found so frequently among the chimney sweeps in England when they used to climb down into the chimneys. This was a typical form of cancer, which in the light of present discoveries may be regarded as of arsenical origin. This special pathology of the coal industry, the symptoms of which were known although the etiology remained obscure (the coal poisoning of Manouvrier), may henceforth be classified among the industrial diseases against which we are thus forearmed. We owe it to the important studies of Bayet that this has been brought about.

These studies deserve to be brought to the attention of all those who are interested in social medicine. The difficulties that are encountered in every country when attempts are made to introduce prophylactic measures against epithelial cancer among workers in pitch are well known. In England, where, since 1910, the question has been carefully considered, the results obtained are still unsatisfactory, as may be seen by the increased incidence of epithelial cancer noted during the period from 1914 to 1918.

Marriages

GEORGE HERMAN ANDERSON, Seattle, to Miss Ruth Weisdorfer of Burlington, Kan., at Chicago, January 10.

PAUL WEGEFORTH, Coronado, Calif., to Mrs. Lillie Holbrook, at San Diego, Calif., January 19.

THURMAN GILLESPIE, Wheeling, W. Va., to Elizabeth Pyatt Bonsted of Philadelphia, December 24.

HARRY JULIUS ISAACS to Miss Edith Lippert, both of Chicago, recently.

Deaths

B. Holly Smith, Baltimore; College of Physicians and Surgeons, Baltimore, 1883; aged 61; a graduate of the Baltimore College of Dental Surgery in 1881; president of the Faculty and professor of oral surgery in the Baltimore College of Dental Surgery; chairman of the oral hygiene council of Maryland; chairman of the executive council of the National Association of Dental Faculties; once president of the Baltimore Dental Club; an extensive contributor to the literature of oral surgery; died, January 22, from heart disease.

Lewis White Callan • New York City; University of Pennsylvania, Philadelphia, 1901; aged 42; captain, M. C., U. S. Army; and in charge of the ophthalmic department of the base hospital at Fort McHenry, Md., and discharged, April 6, 1919; a member of the American Ophthalmological Society, and New York Academy of Medicine; ophthalmic surgeon to the New York Eye and Ear Infirmary, and St. Bartholomew's and Lying-in hospitals; died, January 21, from pneumonia.

John Donnington Bartlett • Major, M. R. C., U. S. Army, Grass Range, Mont., formerly of Galesburg, Ill.; Rush Medical College, 1905; aged 39; at one time health officer of Galesburg; who became of unsound mind while serving with the Expeditionary Forces in France; was brought home, placed under treatment at U. S. General Hospital No. 28, Fort Sheridan, Ill., and then committed to the Watertown State Hospital; committed suicide by strangulation, January 12.

Benjamin Pitcher Brodie • San Francisco; Michigan College of Medicine, Detroit, 1884; aged 60; for many years a surgeon of Detroit; physician to St. Mary's Hospital; attending surgeon to Harper Hospital and Consulting surgeon to the Woman's and Solvay hospitals; chief surgeon of the Grand Trunk system, and Detroit United and Detroit Shore Line railways; died in the Southern Pacific Station, San Francisco, January 23.

George Brown Beach, Scranton, Pa.; Jefferson Medical College, 1886; aged 54; a member of the Medical Society of the State of Pennsylvania; captain, M. R. C., U. S. Army, with service in France, where he obtained the Croix de Guerre, and a citation from the commanding general, and was discharged, June 2, 1919; died in the West Side Hospital, Scranton, December 31, from meningitis.

Albert Woelfel • Chicago; University of Leipzig, Germany, 1902; aged 48; for several years instructor in physiology, and for a time in charge of the physiological laboratory in the University of Chicago; managing director of the Physicians Radium Association of Chicago; died, January 31, from pneumonia following influenza.

Charles Shivers Heritage • Glassboro, N. J.; University of Pennsylvania, Philadelphia, 1893; aged 48; president of the Gloucester County Medical Society in 1917; a specialist in diseases of the eye, ear, nose and throat; president of the Glassboro Loan and Building Association; died, January 4, from nephritis.

Luella M. Schneck, Indianapolis; Medical College of Indiana, Indianapolis, 1895; aged 52; a member of the Indiana State Medical Association; for five years a member of the staff of the Fletcher Sanitarium, and physician to the Indiana Girls' School, Clermont; died, January 21, from heart disease.

Norris Cameron, Indiana, Pa.; Jefferson Medical College, 1880; aged 63; formerly local surgeon of the Pennsylvania system, at Pitcairn, Pa.; burgess of Pitcairn from 1894 to 1897, from 1910 to 1913; for several years director and president of the First National Bank of Pitcairn; died, January 11.

Leander Erastus Maddox, Montpelier, Ind.; University of Michigan, Ann Arbor, 1875; aged 68; for several years a druggist; president, cashier and director of the First National Bank of Montpelier; at one time a member of the local school board; died, January 15, from valvular heart disease.

Curtis Elmer Kelso • Lieut., M. R. C., U. S. Army, Thomasboro, Ill.; University of Illinois, Chicago, 1905; aged 38; on duty at Fort Oglethorpe, Ga.; died in the Post Hospital, Fort Oglethorpe, January 8, from narcotic poisoning.

Justin F. Simonds, Riverdale, Md.; Castleton (Vt.) Medical College, 1851; aged 93; a pioneer practitioner of Iowa; surgeon of United States Volunteers during the Civil War, and from 1902 to 1904 examiner in the United States Pension Bureau, Washington, D. C.; died, January 3.

Thomas Francis Conneen • Portland, Me.; Bowdoin Medical School, Brunswick and Portland, Me., 1901; aged 45; city physician of Portland in 1907, and then appointed medical examiner (coroner) of Cumberland County; died, about January 22, from cerebral hemorrhage.

Alexander H. Koerner, Woodsfield, Ohio; University of Maryland, Baltimore, 1886; aged 61; a member of the Ohio State Medical Association; president of the Monroe County Medical Society; died in the State Hospital, Columbus, Ohio, January 6, from septicemia.

Albert Earl McCallin • Wisconsin Veteran's Home, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1906; aged 53; head surgeon at the Wisconsin Veteran's Home; died from thrombosis, January 17, after operation for duodenal ulcer.

Estes Paine • Major, M. C., U. S. Army; University of Texas, Galveston, 1906; aged 39; formerly surgeon of the Norfolk and Western Railroad; at Bassett, Va.; died in the Walter Reed General Hospital, Takoma Park, D. C., December 9.

Charles Milton Buchanan • Tulalip, Wash.; National University, Washington, D. C., 1890; aged 51; a physician in the United States Indian Service and a worker among the Puget Sound Indians for twenty-four years; died in Seattle, January 18.

Robert Samuel Bentley • Chicago; Northwestern University Medical School, Chicago, 1899; aged 44; a member of the Illinois State Medical Society; was shot and killed, January 27, by a patient, who claims that the shooting was accidental.

David S. McConnaughey, Wayland, Iowa; College of Physicians and Surgeons, Keokuk, Iowa, 1867; aged 82; a veteran of the Civil War; president of the Henry County Medical Society in 1914; died, January 7, from senile debility.

Daniel Webster Hopkins, Havre de Grace, Md.; University of Maryland, Baltimore, 1877; aged 65; for several terms a member of the city council, and at the time of his death public health officer; died, January 16, from heart disease.

Charles Milton Lenhart, Zanesville, Ohio; Miami Medical College, Cincinnati, 1886; aged 56; a member of the Ohio State Medical Association; surgeon to the City and Good Samaritan hospitals, Zanesville; died, January 17.

Stanley Nelson Insley • Grayling, Mich.; Trinity Medical College, Toronto, 1894; aged 49; president of the county society; division surgeon for the Michigan Central Railroad; died, January 7, from pernicious anemia.

Michael Washington Hurst, Talmage, Pa.; University of Pennsylvania, Philadelphia, 1861; aged 81; a member of the Medical Society of the State of Pennsylvania; died in the General Hospital, Lancaster, Pa., January 13.

Adam E. Focht, Great Bend, Kan.; Hahnemann Medical College, Chicago, 1885; St. Louis College of Physicians and Surgeons, 1896; aged 60; a member of the Kansas Medical Society; died, January 8, from heart disease.

Isaac C. Smith, Peel Tree, W. Va.; Kentucky School of Medicine, Louisville, 1876; aged 67; a member of the West Virginia State Medical Association; died from heart disease, January 15, while making a professional call.

Miles Clinton Bristol • Bay City, Mich.; Long Island College Hospital, Brooklyn, 1894; aged 52; for two terms health officer of Bay City and coroner of Bay County; died, January 21, from carcinoma of the larynx.

John G. Koch, Petersville, Pa.; Jefferson Medical College, 1865; aged 77; a member of the Medical Society of the State of Pennsylvania; died, January 8, from the effects of a fracture of the hip two weeks before.

Benjamin W. Cabell, Hampton, Va.; College of Physicians and Surgeons, Baltimore, 1891; aged 55; a member of the Medical Society of Virginia; died in the Dixie Hospital, Hampton, January 13, from nephritis.

Thomas J. Harcourt, Somerville, Ohio; American Eclectic Medical College, Cincinnati, 1889; aged 82; for more than fifty years a practitioner of Tusculum, Cincinnati; a veteran of the Civil War; died, January 15.

Henry A. Minor, Macon, Miss.; University of Virginia, Charlottesville, 1857; aged 83; once president of the Missis-

issippi State Medical Association; died in an infirmary in Hattiesburg, Miss., January 19.

LeRoy J. Beebe, Yakima, Wash.; University Medical College of Kansas City, Mo., 1909; aged 38; house physician at St. Elizabeth's Hospital; died, December 29, four days after an operation for appendicitis.

Robert Pooler Myers, Claremont, Calif.; Savannah, Ga., Medical College, 1860; aged 80; a member of the Medical Society of Hawaii, and for several years a resident of Honolulu; died, January 1.

Agnes Mary Browne, Oakland, Calif.; College of Physicians and Surgeons, San Francisco, 1918; aged 46; died in St. Luke's Hospital, San Francisco, January 13, from myocarditis after a laparotomy.

Alonzo F. Kramps ♂ Chicago; Rush Medical College, 1895; aged 54; for many years a member of the staff of the St. Elizabeth's Hospital; died, January 30, from pneumonia following influenza.

John Austin Kane ♂ Brooklyn; Harvard University Medical School, 1902; aged 41; attending physician to the Angel Guardian Home; a specialist in pediatrics; died, January 23, from pneumonia.

Henry Hopson Wilcox, Montague, Mass.; Cornell University, New York City, 1906; aged 38; a member of the Massachusetts Medical Society; died in Des Moines, Iowa, December 23.

Andres Buckham MacLean, Centralia, Wash.; University of Toronto, 1906; aged 45; a member of the Washington State Medical Association; coroner of Lewis County; died, January 12.

Russel Ross Marble, Hastings, Neb.; University of Michigan, Ann Arbor, 1902; aged 48; died in the Mary Lanning Hospital, Lincoln, January 16, from pneumonia complicating diabetes.

William Pell Ballance, Los Angeles Harbor, Calif.; Washington University; Baltimore, 1873; aged 67; for several years a practitioner of Alaska; died, January 5, from heart disease.

Daniel Kuhn ♂ St. Louis; Washington University, St. Louis, 1865; aged 82; for more than half a century a practitioner of St. Louis; a specialist in pediatrics; died, January 14.

John Clark Patterson, Batavia, Ill.; Northwestern University Medical School, Chicago, 1872; aged 70; died in the Presbyterian Hospital, Chicago, January 11, from pneumonia.

William Cicero Sessoms, Brewton, Ga.; Atlanta (Ga.) Medical College, 1892; aged 53; died at the home of his father in Stedman, Ga., January 8, from cerebral hemorrhage.

Daniel W. Maxson, Galveston, Texas (license, Kansas, 1901); aged 82; for many years a practitioner of Toronto, Kan.; died, January 14, at the home of his son in Galveston.

Oliver Harrison Martin, De Pere, Wis.; Rush Medical College, 1874; aged 85; for more than thirty years a practitioner of Kewaunee, Wis.; also a druggist; died, January 8.

William H. Wagner, York, Pa.; Jefferson Medical College, 1881; aged 67; director of health during the smallpox epidemic in 1900; died, January 3, from aneurysm of the aorta.

Albert William Knott, Montrose, Colo.; Washington University, St. Louis, 1906; aged 43; a member of the Colorado State Medical Society; died, January 2, from tuberculosis.

George Henry Sanborn, Shawnee, Okla.; University of Vermont, Burlington, 1899; aged 46; a member of the Oklahoma State Medical Association; died, about January 7.

Henry William Morgan, Nashville, Tenn.; Vanderbilt University, Nashville, 1875; aged 66; formerly dean of the dental department of his alma mater; died, January 17.

James Ramsay Flood, Mokenca, Ill.; Jefferson Medical College, 1866; aged 81; for many years a practitioner of Chicago; died, January 9, from valvular heart disease.

Charlotta Yhlen Olsen, Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1873; aged about 70; died in Pasadena, Calif., January 14, from heart disease.

Edward Morris Price, Brooklyn, L.R.C.P., London; L.R.C.S., England, and M.R.C.S., England, 1879; University of Brussels, Belgium, 1884; aged 62; died, January 13.

George Nelson Vail, Parker, Kan.; University of Michigan, Ann Arbor, 1869; aged 79; a member of the Kansas Medical Society; died, January 6, from cerebral hemorrhage.

George Harvey McMichael ♂ Buffalo; Niagara University, Buffalo, 1888; aged 63; a specialist in the treatment of alcoholism; died, January 18, from angina pectoris.

Edward L. Blanding, Chicago; Jenner Medical College, Chicago, 1906; aged 55; also a pharmacist; died in Lakeside Hospital, Chicago, January 25, from pneumonia.

John Whiten Merry, Mount Ayr, Ind.; University of Michigan, Ann Arbor, 1869; aged 76; died in the Jasper County Hospital, Rensselaer, Ind., January 1.

Joseph J. McKinney, Rifle, Colo.; St. Louis College of Physicians and Surgeons, 1909; aged 48; died in Pueblo, Colo., January 2, from pernicious anemia.

William S. Brabham, St. Louis; Meharry Medical College, Nashville, Tenn., 1898; aged 50; a colored practitioner; died, November 14, from cerebral hemorrhage.

Milton Hall Leonard, New Bedford, Mass.; University of the City of New York, 1879; aged 63; visiting physician to St. Luke's Hospital; died, January 14.

Josephus S. Graham ♂ Tuckerman, Ark.; Bellevue Hospital Medical College, 1889; aged 54; died in Hot Springs, Ark., January 16, from angina pectoris.

Arthur F. Schulz, Chicago; Dearborn Medical College, Chicago, 1907; aged 41; was found dead in a hotel in Milwaukee, February 1, from pneumonia.

Robert Kells Hackett ♂ Major, M. C., U. S. Army, Los Angeles; Tulane University, New Orleans, 1899; aged 49; died in San Francisco, January 1.

William A. Pease, Otsego, Wis.; (license, Wisconsin, 1899); aged 83; a member of the State Medical Society of Wisconsin; died, January 6.

Orlando S. Wood, Omaha; Hahnemann Medical College, Philadelphia, 1860; aged 87; died at the Home of Hope, Florence, Neb., January 10.

Bruce Frary Halsey, Medina, N. Y.; University of Louisville, Ky., 1901; aged 43; died, January 5, from pneumonia, at a sanatorium in Buffalo.

John Devin Kelly, New Haven; University of the City of New York, 1880; aged 73; died in Hamden, Conn., January 9, from angina pectoris.

John Joseph Walsh, Scranton, Pa.; Jefferson Medical College, 1886; aged 58; died, December 31, as the result of an automobile accident.

Willard Channing Brown ♂ Detroit; University of the City of New York, 1861; aged 62; died, October 18, from acute nephritis.

William P. Sydnor, Burgess Store, Va.; Washington University, Baltimore, 1874; aged 78; died, September 19, from senile debility.

Samuel Freeman ♂ Trenton, N. J.; University of Pennsylvania, Philadelphia, 1899; aged 43; died, January 13, from pneumonia.

John Henry Gifford ♂ Fall River, Mass.; Harvard University Medical School, 1884; aged 61; died, December 14, from myocarditis.

Henry K. Cunningham, La Plata, Mo.; College of Physicians and Surgeons, Keokuk, Iowa, 1874; aged 84; died, January 7.

Thomas Walter Clarke, Philadelphia; Hahnemann Medical College, Philadelphia, 1896; aged 46; died, January 8, from nephritis.

Alfred Hall Perrie ♂ McKendree, Md.; Baltimore Medical College, 1895; aged 48; died, January 14, from heart disease.

Steven H. Hurst, Laconia, Ind.; University of Louisville, Ky., 1889; aged 63; died, January 13, from heart disease.

William Clarence Benjamin ♂ Hornell, N. Y.; University of the City of New York; 1887; aged 60; died, January 9.

William Lawton Evers, New York City; Bellevue Hospital Medical College, 1892; aged 74; died, January 17.

George Augustus Sigler, Indianapolis; Bellevue Hospital Medical College, 1879; aged 73; died, January 18.

Pasquale Monaco, Chicago; University of Naples, Italy, 1910; aged 59; died, January 22, from influenza.

Orson Hyde Crandall, Quincy, Ill.; Eclectic Medical Institute, Cincinnati, 1867; aged 93; died, January 17.

Lamont H. Ross, Lewisburg, Pa.; University of Buffalo, N. Y., 1892; aged 53; died, January 9.

John Hood, Baltimore; University of Michigan, Ann Arbor, 1858; aged 81; died, December 26.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

GRALE'S FRUIT LAXATIVE

"Grale's Fruit Laxative" put out by the Grale Packing Co., Roselle, N. J., is advertised under the claim that it contains no drugs:

"Grale's Fruit Laxative contains only figs, dates, raisins and prunes, a few simple herbs and bran. NO DRUGS AT ALL."
". . . this is a food—not a drug. . . ."

The preparation was submitted to the A. M. A. Chemical Laboratory for the purpose of determining whether or not the claim that the stuff contained no drugs was justifiable. The laboratory report follows:

"Grale's Fruit Laxative" is a soft, brown solid with an odor and taste suggestive of figs and prunes. Chemical examination indicated the presence of an emodin-bearing drug, or its extractives, in considerable amounts. This was shown by further tests to be neither aloes, cascara nor rhubarb. Microscopic examination revealed the presence of ground senna in the mass. Since senna is a well known drug of recognized therapeutic activity, the declaration on the label of Grale's Fruit Laxative that the preparation contains no drugs is false.

DIONOL—THE GLORIFIED PETROLATUM

An Indiana physician sends us in a batch of leaflets detailing the marvels of "Dionol" and thus comments:

"I received the enclosed in the mail today and I am puzzled, perplexed and astounded. I had formed the opinion that the profession was getting better; that it was more scholarly than formerly when the two course school was still in existence and any one could matriculate; that it was no longer possible for a 'patent medicine' manufacturer to palm off his wares on us. After reading this stuff and realizing that such methods must be remunerative, I am deeply humiliated. Is it possible that educated physicians respond to this kind of advertising? Or has some one perpetrated a joke on me? If the profession can be thus successfully exploited one can no longer wonder at the following which every new 'ic' and 'ism' acquires."

It is a pity that the medical profession generally does not react to the Dionol and similar advertising as does our correspondent. As the concern continues to do business, the presumption is that at least some physicians are using Dionol. As was pointed out in THE JOURNAL of Jan. 26, 1918, Dionol seems to be a glorified and esoteric form of petrolatum. The exploitation of Dionol is based on the following theory: (1) The brain is a generator of neuro-electricity, (2) the nerves are the conductors of this electricity, (3) the nerve sheaths are the insulators, (4) wherever there is local inflammation the nerves are short circuited, due to a breaking down of the insulation resistance of the nerve sheaths, (5) this results in "an escape of neuro-electricity," (6) Dionol coats the nerve sheaths with a nonconducting layer and this restores the insulation and "stops the leak."

Whether this ingenious theory was invented to lend an air of verisimilitude to an otherwise bald and unconvincing tale and give a "reason for being" for Dionol or whether Dionol was first invented and it became necessary to evolve a theory that would give some plausibility to the claims made for this

etherealized petrolatum, we are unable to say. In any case the theory and the product are exploited together.

Among the material sent in by a correspondent are some "Dionol Case Reports." Neither the names nor the addresses of the physicians making these reports are given, but the company states that they may be had "on request." One special "report" is featured under the heading "Infected Wound. Striking Results After United States and French Government Army Surgeons Failed" is signed "Dr. W." It is dated July 19, 1919. A few months ago the Dionol Company was sending out this same testimonial with the full name and address of the "doctor" giving it. Investigation showed that the "doctor" in question was an osteopath whose specialties, according to his advertisement in his local newspaper are "Catarrhal Deafness and Hay Fever, Acute and Chronic Diseases"! In this connection it is worth noting that investigation of some of the earlier testimonials sent out by the Dionol concern and alleged to have been given by "doctors" showed that the gentlemen in question were "drugless healers."

As a "true indication of the value which the medical profession is placing on Dionol" the Dionol Company has published the names of some physicians who, it is alleged, have used the preparation. Here, arranged geographically, are some of the "prominent physicians throughout the country," who are said to have had "remarkable success" with Dionol:

BALTIMORE, Md., Dr. O. N. Duvall.
BOSTON, Mass., Dr. A. H. Flower.
CHICAGO, Ill., Dr. Frank W. Klocke.
DETROIT, Mich., Dr. J. A. Bullock.
DETROIT, Mich., Dr. P. L. Lathrop.
DETROIT, Mich., Dr. C. G. Morris.
DETROIT, Mich., Dr. E. A. McCosh.
DURAND, Wis., Dr. R. G. Healy.
DRYDEN, N. Y., Dr. M. L. Briggs.
GOSHEN, Ind., Dr. R. L. Starkweather.
GRAND RAPIDS, Mich., Dr. L. R. McCready.
MINERAL WELLS, Texas, Dr. R. H. Lindley.
MOUNDVILLE, Mo., Dr. G. Schaff.
MUSCOGEE, Fla., Dr. A. J. Johnson.
OKLAHOMA CITY, Okla., Dr. G. S. Pettit.
PITTSBURG, Pa., Dr. H. J. Dorrance.
PITTSBURG, Pa., Dr. J. E. Johnston.
SEDAN, Kans., Dr. F. W. Wells.
SOUTH BEND, Ind., Dr. H. A. Fink.
SPRINGFIELD, Ill., Dr. Emery Emnis.
WILMAR, Minn., Dr. Oscar Zabr.

HYPNO-BROMIC COMPOUND

A physician in Vermont writes:

"This is simply a word of inquiry—and of possible warning to other practitioners—regarding a preparation known as Hypno-Bromic Compound manufactured by H. K. Wampole & Co. This compound is dispensed by druggists without prescription and contains in each ounce:

"Cannabis indica	1 gr.
"Morphin	¼ gr.
"Potassium bromid	48 gr.
"Hyoscyamus	1 gr.
"Chloral hydrate	96 gr.

"I have at the present time three young women who are addicts to this preparation as the result of thoughtless prescriptions from physicians. This mixture evades the working of the Harrison Act and may be dispensed freely at the discretion of the druggist and, as a result, these three cases of mine have been able, by visiting the various drug stores in town, to keep an ample supply on hand at all times."

"Hypno-Bromic Compound" is more than an unscientific mixture; it is a dangerous product and should not be sold indiscriminately over the drug counter. Before the Harrison Narcotic Law went into effect, "Hypno-Bromic Compound" contained half a grain of morphin sulphate to the ounce instead of its present one-fourth grain. Physicians remember that Section 6 of the Harrison law contains a joker—put over by the "patent medicine" interests—that exempts proprietary remedies containing one-fourth of a grain of morphin or less to the ounce from the restrictions of that Act. While it is illegal for a physician to write a prescription which contains morphin, no matter how small the amount, unless he conforms in all ways to the requirements of the Harrison Narcotic Law, "patent medicine" concerns can sell indiscriminately nostrums containing morphin up to this amount and the public can buy them without let or hin-

drance. No reputable druggist would sell a layman over seven hundred grains of chloral hydrate or two grains of morphin or eight grains of extract of cannabis indica, without a prescription, yet, the druggist may hand over 8 ounce bottles of Hypno-Bromic Compound which contain 768 grains of chloral hydrate, 2 grains of morphin sulphate, 8 grains of extract of cannabis indica, 8 grains of hyoscyamus and 384 grains of potassium bromid! Physicians who prescribe such products as Hypno-Bromic Compound and druggists who indiscriminately sell such stuff are disgracing two honorable professions.

Correspondence

RECOGNITION OF A GREAT MEDICAL CAREER

To the Editor:—In our country there are few formal means for recognizing in any public way the services of a great physician or a great teacher. In the older countries such services have been recognized by the bestowal of honors, or nobility or grants of money, or by other official means which call attention to the services rendered. In our country no recognition through official orders may be given, and we are glad to have it so, because, admirable as such prizes are when worthily bestowed, they become too often the playthings of political favor or of personal privilege.

In the case of Dr. Christian R. Holmes, whose death the medical profession deploras, action has been taken by the Carnegie Corporation of New York to give notable recognition of his services to the science of medicine and to medical education. Immediately after his death the Carnegie Corporation appropriated \$250,000 to the University of Cincinnati for the endowment of a chair of clinical medicine to bear forever the name of the Christian R. Holmes Chair of Medicine. The information concerning this action was conveyed to the University of Cincinnati in the following telegram signed by Hon. Elihu Root, chairman of the board:

The trustees of the Carnegie Corporation of New York at their meeting held this day have appropriated the sum of two hundred and fifty thousand dollars which they tender to the Medical Department of the University of Cincinnati to endow the chair of clinical medicine in honor of Christian R. Holmes and to bear his name. This action is in recognition of Dr. Holmes' great service to medical education.

Every man who is interested in the progress of the medical profession and who knows of the intelligence and devotion that Dr. Holmes gave to his work will feel a sense of satisfaction at this recognition. Philanthropists and endowed foundations that give money for the promotion of science and education generally attach to their gifts conditions which require the institution or individual to raise additional means. In this instance the Carnegie Corporation makes no conditions but tenders this money generously and heartily, to commemorate the service of a physician of Cincinnati to his city, to his state, and to the nation. It is a fine thing for a great foundation to make such a hearty and spontaneous tribute to the service of Dr. Holmes. In the opinion of the corporation, he has rendered a notable service to medicine and to medical education. A dozen years ago, medical teaching in Cincinnati was in the same condition as in all our great cities; the work was carried on oftentimes unselfishly, sometimes from professional motives; but in the main, medical teaching was a by-product of medical practice. Dr. Holmes was a member of that group of American physicians and surgeons who helped to bring about a new conception of medical teaching and to lift our medical schools free from commercialism. Through his efforts and those of other men equally devoted, there is in Cincinnati a medical school, a part of a university, having high standards and scholarly outlook. There was built through Dr. Holmes' exertion one of the great public hospitals of the world, planned after a study of all the hospitals of Europe and America. This hospital, although a municipal hospital, is under the control of the University of Cincinnati College of Medicine, and politics has been completely eliminated from its management.

The medical school stands adjoining the hospital, and together they offer most admirable clinical opportunities for medical students. The University of Cincinnati College of Medicine promises to be one of the great medical schools of the world. To have wrought this work with such farsightedness, such scientific sincerity, and with such success as Dr. Holmes did, was to render a notable service to medicine and to medical teaching, and it is this service which the Carnegie Corporation desired to honor.

Other men in Cincinnati worked for the same ideals and contributed to the same purpose. Dr. Holmes would be the first to wish that they might receive full credit. His service would have been impossible without their support and cooperation, or without the consistent and able support of President Dabney of the University of Cincinnati. The Carnegie Corporation of New York forgets none of these things, but the trustees felt sure that every physician and every teacher who has wrought in the medical schools of Cincinnati will agree that there should be a special testimonial to him whose leadership and whose devotion have resulted in such fruitful results for his city and for his country.

HENRY S. PRITCHETT, New York.

President, Carnegie Foundation for the
Advancement of Teaching.

THE MEDICAL RESERVE OFFICER

To the Editor:—Referring to the interesting article by Dr. Louis J. Hirschman in THE JOURNAL, January 3:

Individual injustices regarding rank were inevitable in the rapid expansion of the Medical Corps to about fifty times its original number. Correction of errors was under way when the war ceased; but military machinery moves slowly, and deliberate action was necessary to avoid fresh errors.

So far as the limitation of medical rank to major and of line rank to colonel, the M. C. duties corresponding to higher rank are very different and require long military experience. A fairly adequate supply of experienced men was available in the regular establishment, and subordinate positions requiring mainly professional skill could be filled from civilian life. In the line, duties at least as far as colonel are a logical and fairly simple extension of those of lower ranks for which the regular army could not have provided without undue promotion of immature officers. An adequate supply was available among national guard officers of long experience, while civilian physicians who had had any kind of military experience fitting them, for example, to conduct a base hospital, were very few.

For raw material, trained at camps, the medical profession had a distinct advantage in rank compared with any other class. All entered at least as first lieutenants, while most line officers graduated as second lieutenants. Many of the former were captains and majors, while the few line officers who entered active duty as majors were instances of influence or native ability. So far as I can judge, even the rank on discharge at the end of war averaged higher for medical men than others, not even excluding national guardsmen of long antebellum experience.

The limitation of rank in the (reserve) medical corps was abrogated fairly early in the war, both in theory and in practice, and did not at the beginning apply to such national guard surgeons as were eligible to the rank of lieutenant colonel (division surgeon). The profession actually received a good many commissions higher than the majority, at least one brigadier-generalship; and in another year, of war, a still better showing would have been made.

The implication that the reserve surgeon would have been better off either as to proficiency, efficiency or personal comfort under amateur superiors, is, so far as my experience and observation goes, entirely contrary to fact.

The general complaint of surgeons from civilian life who served in the war depends not on the matter of rank but on the essential differences between civilian and military regulations and customs. How far the latter can be modi-

fied to suit men from civil life in a great military emergency is a problem too complicated to discuss here, and I am rather inclined to believe that Mahomet will have to go to the mountain instead of trying to get the mountain to come to him.

The problem would have been solved to a large degree practically if, instead of thinking so much about rank, men who were only temporarily in military service had continued to think of themselves as physicians, had limited their conception of rank to necessary authority, and had not carried it into strictly professional matters, as the establishment of diagnoses, arbitrary regulation of therapeutics and claiming of right to operate, but had demanded and practiced the spirit of professional loyalty supposed to pertain to their life work.

A. L. BENEDICT, M.D., Buffalo.

COMPULSORY HEALTH INSURANCE

To the Editor:—In THE JOURNAL, Jan. 24, 1920, p. 271, Dr. E. M. Stanton opposed the principles of compulsory health insurance on the grounds that the burdens of such insurance cannot be borne by the insured. In so doing, in my opinion, he made a very good argument in favor of compulsory health insurance.

It is precisely because modern scientific medicine, as practiced today, is too expensive for any except the very rich that some system must be evolved to diminish the expense to the individual.

If Dr. Stanton seriously believes that the wage earner in general receives adequate medical attention under the present system he is, naturally, opposed to any form of health insurance. A few physicians who emphasize the fact that prolonged illness in persons of limited income almost universally leads to the support of the individual either by the state or by charitable institutions believe that health insurance will diminish the demands made on charity.

Health insurance will decrease the demands made on charity because it will cause: (1) the distribution of the economic loss due to enforced idleness as a result of illness, and (2) a diminution in preventable illness which will occur as a consequence of earlier diagnosis and treatment.

Unless it is believed that we are accomplishing everything possible toward the prevention of disease, there is no excuse for opposition to a measure which is proposed in the effort to afford earlier and better medical care for a large percentage of individuals in a given community. Criticism to health insurance should at least suggest the alternative.

Dr. Stanton quotes the General Electric Mutual Benefit Association as "one of the best sickness insurance policies ever offered," and prefers it to the Davenport bill. Unfortunately, not all workmen can be employed by the General Electric Company or by the Ford Motor Company, which also makes excellent provision for sick or injured employees. It is precisely because it is desirable to give every employee the protection that is now given by certain of the more progressive industrial corporations that compulsory health insurance has been advocated.

If the General Electric Company has the best plan of sickness insurance, by all means let us advocate such a plan. If universal care of the community by the state board of health is preferable to any form of insurance, then it should be favored. But let us not oppose constructive legislation for the benefit of the sick unless we can offer something better.

Private practice and organized charity, together with the excellent state organizations for public health, do not today solve the problem of medical care for the wage earner, as the records of any charitable organization will clearly demonstrate.

A. C. BURNHAM, M.D., New York.

The Public's Help.—No big step in social progress is possible without the active sympathy of large masses of the community, and in this respect the movement for improving the national health has the greatest support.—Brend.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

SURRENDER OF WAR TERM INSURANCE

To the Editor:—I desire some information about war risk insurance. Will the Bureau of War Risk Insurance refund all or part of the premiums paid after discharge from the service to any one who wishes to discontinue his insurance? I wrote the bureau and asked this information, but received an evasive answer along with advice that I had better reconsider my decision on account of the numerous advantages, etc., etc. The letter was a "ready made" one, like all correspondence of the bureau, my name and address being merely inserted to fit the contents.

I was honorably discharged from service late in 1918, and hoping to be able to convert my policy into a standard government peace time policy, I paid my war time premiums regularly and faithfully each month as due, up to and including September, 1919. I was continually annoyed by notices from the bureau that my policy had lapsed, in spite of the fact that I had receipts for premiums and was paid up to date and continued to receive receipts month by month. I wrote the bureau three or four times asking an explanation, and each time had to wait from four to six weeks for a reply which, as usual, dodged my question and enumerated the many advantages of holding on to one's policy, etc., etc. Then the bureau sent five different premium receipt-notices, also a few lapse notices sprinkled in, to the address of my beneficiary, in a far away land across the sea. Note, I had already received, and was then receiving, correspondence from the bureau at my correct address in America. Their very latest stunt was to address me by my first and middle name only, making a surname out of my middle name, and reduplicating the initial of my middle name. By extraordinary intelligence on the part of the local post office, the letter reached me safely. I cannot think but that the Bureau of War Risk Insurance is a marvel of inefficiency. For this reason, and because I was financially unable to convert my policy, I became thoroughly disgusted, and wished I had dropped my insurance when I was discharged. So in October, 1919, instead of paying a premium as usual, I wrote and asked the bureau the question I have asked you. Under date of November 24, they answered as I described. Perhaps you can give me the information I desire, since I cannot get it from the bureau.

M.D., Ind.

ANSWER.—Our correspondent's letter was referred to the Bureau of War Risk Insurance, which replies: "A man who kept up his insurance after discharge has received full value for the premiums paid in that he has received protection for the time covered by his premiums. The war term insurance has no surrender value except an amount equivalent to the unearned premium paid in. A premium notice is sent to each policy holder as a reminder that the premium should be paid. If it has been paid already, the notice should be disregarded. In some instances, premium notices may be forwarded after the premium payment has been received, but before it has been posted to the insured's account." The director of the bureau states that he does not feel that a clerical error, even though annoying, should cause a man to demand his insurance policy or allow it to lapse. Government life insurance is backed by all the resources of the United States government, and is not only the safest but the cheapest insurance with similar benefits obtainable. Our correspondent is also requested to communicate directly with Mr. R. W. Emerson, Assistant Director of War Risk Insurance, who will make a special investigation of his case.

FILARIASIS—TROPICAL DISEASES

To the Editor:—1. Please let me know what is the latest treatment for filariasis.

2. What is the best book on tropical diseases?

A. C. VIEIRA DA CUNHA, M.D., Recife, Brazil.

ANSWER.—1. Drug treatment of filariasis, according to Manson and others, is uniformly disappointing. The drugs that have been recommended in the treatment of this disease are gallic acid or benzoic acid in large doses, glycerin, the tincture of ferric chloride, decoction of mangrove bark, chromic acid, quinin, sodium salicylate, ichthyol, *Nigella sativa*, thymol, and methylene blue. R. G. Lee (*Crónica méd.-quir. de la Habana* 44:15 [Jan.] 1918) reported excellent results in eighteen cases of filarial hematuria treated with potassium iodid. Leonard Rogers (*Lancet* 2:604 [Oct. 4] 1919) found that repeated injections of safe doses of sodium antimonyl tartrate, 1:50 solution, produced diminution of filarial embryos in the peripheral blood. Jeanselme (*Bull. Acad. de méd.* 81:156 [Feb. 4] 1919) and Deschamps (*Bull.*

Acad. de méd. 81:655 [May 20] 1919) have reported radical cures after intravenous injections of arsphenamin. Special treatment will naturally depend on the manifestations in a given case. Lymphangitis with fever requires rest, elevation of the affected part, ice or cooling lotions or warm fomentations locally, opium or morphin when necessary to relieve pain, mild aperients, and if tension is great, pricking or scarifying of the swollen area. Lymph scrotum should be kept scrupulously clean, powdered, suspended and protected against irritation or injury. Chyluria demands absolute rest, elevation of pelvis, restriction of fluid and food—especially fats—and gentle purgation. In elephantiasis of extremities, elastic bandages, massage and elevation of the part are indicated. Any or all of these conditions may necessitate surgical interference for the relief of an incapacitating amount of discomfort or frequent inflammatory attacks with fever.

2. There are several excellent texts on tropical medicine, among which are:

- Manson, Sir Patrick: *Tropical Diseases*, Ed. 5, Pp. xxiv+937, New York, William Wood & Co. 1914.
 Castellani, Aldo, and Chalmers, A. J.: *Manual of Tropical Medicine*, Ed. 2, New York, William Wood & Co., 1913.
 Stitt, E. R.: *The Diagnosis and Treatment of Tropical Diseases*, Ed. 2, pp. xiii+534, Philadelphia, P. Blakiston's Son & Co., 1917.
 Handbuch der Tropenkrankheiten, herausgegeben von Prof. Dr. Carl Mense, Ed. 2, Leipzig, J. A. Barth, 1913.
 Traité pratique de pathologie exotique, publiée en fascicules sous la direction de MM. C. Grall et A. Clarac, Paris, J. B. Baillière et fils, 1910-1913.

EUPAD AND EUSOL

To the Editor:—Please publish the formula for preparing eusol. This preparation was extensively used by the medical officers in the British army in France.

F. P. SALLEY, M.D., Union, S. C.

ANSWER.—In 1915, Prof. Lorrain Smith and co-workers published a report on the "Antiseptic Action of Hypochlorous Acid and Its Application to Wound Treatment" (*Brit. M. J.* 2:124 [July 24] 1915) wherein they described (1) a powder consisting of an intimate mixture of equal parts by weight of boric acid and chlorinated lime ("bleaching powder") to which was given the name "eupad"; (2) a solution prepared from the same ingredients as those of eupad, which was termed "eusol." This solution may be made in either of two ways:

(a) Twenty-five grams of eupad are shaken with 1 liter of water, allowed to stand for a few hours, and then filtered through cloth or filter paper.

(b) To 1 liter of water add 12.5 gm. of chlorinated lime ("bleaching powder"), shake vigorously, then add 12.5 gm. boric acid powder and shake again. Allow to stand for some hours, preferably overnight, then filter, and the clear solution is ready for use.

In the foregoing formulas (of Smith et al.) for eusol, commercial chlorinated lime was employed, which contained about 25 per cent. available chlorin, whereas the official chlorinated lime is required to assay 30 per cent. in both Great Britain and the United States. Therefore when the official product is used a smaller quantity should be sufficient, namely, 10 gm. of chlorinated lime U. S. P., instead of 12.5 gm. of the commercial product. The name "eusol," we understand, is a contraction of the words "Edinburgh University solution."

LITERATURE ON ELECTRIC SHOCK

To the Editor:—Please give me the titles of literature bearing on burns, death, etc., from electric shock.

GLENN E. WRIGHT, M.D., Woodstock, Ill.

ANSWER.—References to the literature on electric shock were published in *THE JOURNAL*, March 15, 1913, p. 851, and Feb. 27, 1915, p. 763.

The following titles have since accumulated:

- Ingalls, H. A.: Remote Effects of Electric Shock, *New Mexico M. J.* 15:185 (Feb.) 1916.
 Kirmisson, E.: Brulures multiples par l'électricité; hémoglobinurie; morte rapide à la suite de convulsions, *Bull. et mém. Soc. de chir. de Paris* 42:1887, 1916.
 Bayliss, W. M.: The Dangers of Electrical Currents, *Nature* (London) 100:24, 1917.
 Micremet, C. W. G.: Death from Electric Shock from Lucandeseul Bulb, *Nederlandsch Tijdschr. v. Geneesk.* 2:1951 (Dec. 1) 1917; abstr. *THE JOURNAL*, March 2, 1918, p. 661.
 Tornaghi, E.: Polyneuritis Following Electric Shock from Live Wire, *Brazil Med.* 31:175 (May 26) 1917; abstr. *THE JOURNAL*, July 28, 1917, p. 393.
 Lewis, D.: Electric Burn Causing Necrosis of Skull, *Ann. Surg.* 67:149 (Feb.) 1918.

 MASSACHUSETTS: Boston, March 9-11. Sec., Dr. Walter P. Bowers, Room 144, State House, Boston.
 NATIONAL BOARD OF MEDICAL EXAMINERS: St. Louis and Chicago, Feb. 18-25. Sec., Dr. J. S. Rodman, 1310 Medical Arts Bldg., Philadelphia, Pa.
 NEW HAMPSHIRE: Concord, March 11-12. Sec., Dr. Charles Duncan, Concord.
 VERMONT: Burlington, Feb. 10-12. Sec., Dr. W. Scott Nay, Underhill.

NEW FEATURES IN SANATORIUM ARCHITECTURE

Hospital and sanatorium architecture is in a very fluid state, owing in part to the development of fresh air treatment of tuberculosis and to the rapid multiplication of sanatoriums

Fig. 1.—Typical floor plan of a two-story, eight-room cottage. There are a toilet and bath on each floor, and a closet and sleeping porch to each room.

and hospitals. The main point of recent advance is the recognition that while the grouping of patients in large wards promotes economy of administration, it lessens privacy and homelikeness. This is an important consideration, particularly in cases requiring treatment extending over long periods of time, and also in the handling of acute respiratory conditions. We have recognized that the old grouping *en masse* of patients was not best. The formation of cubicles by hanging sheets between beds will no doubt arouse the ingenuity of hospital architects to devise more permanent arrangements to produce the desired protection. The public and the profession have been educated as to the value of fresh air. It is a well recognized fact that the good accomplished for the consumptive patient by sanatorium treatment is directly to his general condition and only indirectly to his lesion. Many existing institutions appreciating this fact are opening windows, putting cubicles around certain patients, and using piazzas and roofs for convalescent patients.

It is in the architecture of new institutions, however, that we look for the greatest advance. Facilities must be furnished for providing patients with fresh, cool air, and also with warmth when they are fed, bathed or dressed. The sleeping porch, an American invention, has become practically universal in tuberculosis sanatoriums. Prior to 1900, the few existing tuberculosis institutions followed the hospital idea of rooms or wards; but with the development of the

Fig. 2.—Plan of principal floor, main building: patients' suites grouped around dining room, office, kitchen, service room and storage. Each suite consists of bedroom, closet, sleeping porch and bathroom.

sleeping porch and cottage buildings at the Trudeau Sanatorium, sanatorium architecture became an entity. Following this, the nation-wide campaign against tuberculosis was organized and there was rapid development of local and state sanatoriums. The apparent necessity for lower cost of building and administration led to the adoption of the so-called "lean to" or King shack plan for ambulant patients.

In 1905, the idea of the individual room and sleeping porch was elaborated in the erection of several eight-room, two-story cottages at the Cragmor Sanatorium, Colorado Springs. A typical floor plan of these cottages is shown in Figure 1. It is quite simple as applied to a small building.

ADDITION TO CRAGMOR SANATORIUM
COLORADO SPRINGS, COLORADO
MR. LARSEN & KITCHEN, ARCHITECTS

Fig. 3.—This addition will be connected with the existing building by a corridor so as to utilize the kitchen service. The jog in the wall gives each inside room two outside fronts and secures privacy for the sleeping porch. Each unit opens directly on the corridor.

The arrangement was satisfactory from an administrative standpoint as well as from that of the patient, and it was later carried into effect in a large three-story building, the principal floor of which is shown in Figure 2. This building, in addition to suites for patients, contains dining room, offices, kitchen, service room and storage. The arrangement provides for each room a bath, a closet and a sleeping porch that opens on two sides. As a still further development of this idea a new building, the ground floor plan of which is shown in Figure 3, is to be erected adjoining the main building (Fig. 2) in order to receive direct service from the

kitchen. The new addition will be built 30 feet to the south-west of the existing building, and will be connected to it by a closed corridor 6 feet 6 inches wide. It will be three stories high. On the ground floor will be located the laboratory, roentgen-ray department, physician's offices and four patients' units. The center of the first floor is taken up by a large sitting room with closed porch, a diet kitchen and chart and service rooms. The second floor is composed exclusively of patients' units. Each unit consists of a room 12 feet by 10 feet 6 inches, a sleeping porch 10 feet 2 inches by 8 feet 9 inches, a bathroom, and a clothes closet. It is to be noted that the rooms are well ventilated and that each room has an individual sleeping porch open on two sides. The doors are amply wide to permit the beds being moved in and out. The sleeping porches are so arranged as not to overlook each other, thus insuring privacy. Each suite has its bathroom. The plan is an attempt to give patients the privacy and comfort they have in their homes, along with fresh air and the care and supervision that can be provided only in an institution.

Wyoming June and October Examination

Dr. J. D. Shingle, secretary of the Wyoming State Board of Medical Examiners, reports the written examinations held at Cheyenne, June 23-25 and Oct. 6-8, 1919. The examinations covered 10 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 19 candidates examined, 11, including 1 osteopath, passed, and 8 failed. Sixteen candidates were licensed by reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
George Washington University	(1906)	77
Chicago College of Medicine and Surgery	(1916) 75.7,	(1918) 78.6,	79.1
College of Physicians and Surgeons, Chicago	(1897)	83.6
Northwestern University	(1906)	81.2
College of Physicians and Surgeons, Keokuk	(1887)	75.3

* Failed at both June and October examinations.

New Hampshire September Examination

Dr. Charles Duncan, secretary of the New Hampshire State Medical Board, reports the written examination held at Concord, Sept. 11-12, 1919. The examination covered 11 subjects and included 80 questions. An average of 75 per cent. was required to pass. One candidate, an osteopath, took the physician's and surgeon's examination and passed. Ten candidates were licensed by reciprocity. The following colleges were represented.

College	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Illinois	(1918)	Illinois

Illinois September Examination

Mr. F. C. Dodds, superintendent of registration, Illinois Department of Registration and Education, reports the written and practical examination held at Chicago, Sept. 22-25, 1919. The examination covered 10 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 78 candidates examined, 53 passed and 25 failed. Twenty-eight candidates were licensed by reciprocity. The following colleges were represented:

Book Notices

THE FUTURE OF MEDICINE. By Sir James Mackenzie, F.R.S., M.D., F.R.C.P., Consulting Physician to the London Hospital. Cloth. Price, \$3.40. Pp. 238. New York: Oxford University Press, 1919.

Scattered through the numerous writings of Sir James Mackenzie are many opinions concerning various aspects of medical education and practice. These statements, most of them critical or suggestive, have been collected, amplified and arranged in orderly sequence and go to make up the present volume. The motif of the book is that the opportunities for investigative work in medicine of the future lie not with the hospital physician or the laboratory man but with the general practitioner. He alone, Mackenzie contends, can learn to appreciate at their true value the symptoms of disease; he is the one best qualified to study the effects of drugs, and other remedial agents on sick human beings; he is the only one who by force of circumstances is permitted to observe disease in its incipience and to discover methods of prevention; he is the one who, relying not on instruments of precision or on supposedly accurate laboratory tests or reports of specialists but rather on his well-trained five senses and his judgment ripened by years of experience, learns to recognize such disease with a certainty and an acumen denied to others. Many illustrative examples are cited, drawn largely from Mackenzie's well-known productive investigations on diseases of the heart. There is so much of truth in what he says, so often with sure touch does he locate the disease spot in our system of education or of practice, so keenly does he lay bare our own personal weakness and so clearly does he point out the way of reform—for his criticisms are constructive as well as destructive—that one must perforce be stimulated and benefited by the reading of the book. But one cannot always agree with him. His condemnations of hospital physicians, bacteriologists and other specialists, laboratory experts, and instruments of precision are too sweeping. The truth of many statements, taken even with the context, may well be questioned; many should be viewed rather as expressions of opinion than as demonstrable facts. One gets the impression of a limitation of the field of vision in the author, a certain provincialism that might not have been had he had a wider acquaintance with the world's medical literature, a more extensive practical acquaintance with great medical men and methods in hospitals and laboratories in the metropolis and in lands other than his own, and if all this had happened early in his medical career. Was it not Samuel Johnson who said you might make a good deal out of a Scotchman if you caught him when he was young? We owe much to Sir James Mackenzie; he is deservedly a leader in British medicine; we welcome his advice and criticism; but we do wish he did not leave on us the impression that he feels that the whole medical world is out of joint and that he seems born to set it right.

THE CONDENSED CHEMICAL DICTIONARY. A reference volume for all requiring quick access to a large amount of essential data regarding chemicals, and other substances used in manufacturing and laboratory work. Compiled and Edited by The Editorial Staff of the Chemical Engineering Catalog. F. M. Turner, Jr., Technical Editor, D. D. Berolzheimer, W. L. Cutler, and John Helfrich, Assistant Editors. Cloth. Price, \$5. Pp. 525. New York: The Chemical Catalog Company, Inc., 1919.

This book is stated to be "a reference volume for all requiring quick access to a large amount of essential data regarding chemicals and other substances used in manufacturing and laboratory work." The book has evidently been compiled by engineers rather than by pharmaceutical chemists, since the information which might appeal to physicians is unreliable. As illustrations of the numerous misstatements found throughout the work, these may be instanced: The strength of the U. S. P. hydrocyanic acid is given as 10 per cent.—an unpardonable error; that of U. S. P. hydrobromic acid as 40 per cent.; the statement is made that cascara bark loses its cathartic properties on being kept for one year; that magnesium sulphate is soluble in alcohol; that monobasic

sodium phosphate is described in the U. S. Pharmacopeia; also the formula given for homatropin hydrobromid is not the generally accepted one. A number of substances well known in modern medicine, such as procain (novocain), stovain and arspenamin (salvarsan) are not described, while substances that have no place in rational therapeutics, such as horseradish, tonga, sunflower and trailing arbutus, are described as medicines. The technical uses of barium sulphate are described, but its use in roentgenologic diagnosis is not mentioned. The book is of little value to physicians. It might have been of some value to them if it had been critically edited and if the pharmacologic actions of drugs had been briefly stated. In the tabulation of "uses" as printed, no extra space would have been required to insert such words as "emetic," "cathartic," "diuretic," etc., in addition to the single word "medicine."

THE ERRORS OF ACCOMMODATION AND REFRACTION OF THE EYE AND THEIR TREATMENT. A Handbook for Students. By Ernest Clarke, M.D., F.R.C.S., Ophthalmic Surgeon to the King George Hospital. Fourth edition. Cloth. Price \$2.50. Pp. 243, with 92 illustrations. New York: William Wood & Co., 1918.

This is the fourth edition of this admirable book, the first edition having been published fifteen years ago, based on lectures delivered at the Central London Ophthalmic Hospital and the Medical Graduates' College. For an established ophthalmologist the book is of little value, as without a knowledge of the fundamentals that it contains he would hardly be competent to practice this specialty. But for medical students preparing to practice ophthalmology, it is of very practical value. A thorough knowledge of the optical properties of the eye, the different forms of ametropia, the mechanism of accommodation, and the methods of refraction are the first essentials to be mastered before one should attempt to deal with the pathology and treatment of eye diseases. The author has arranged these various subjects in a logical way, and, omitting nonessentials, presents the subject matter clearly and concisely. There can be nothing essentially new or original in a treatise of this kind, so that the merit it deserves is due to the author's happy arrangement of the text and the clear elucidation of the subject, which makes it a work of real value to the student of ophthalmology.

WAR SURGERY FROM FIRING-LINE TO BASE. By Basil Hughes, D.S.O., M.A., M.B., and H. Stanley Banks, M.A., M.B., Ch.B., with Special Chapters by Lieut.-Colonel L. F. Smith, C.M.G., R.A.M.C., and Miss C. Bilton, R.R.C., Q.A.I.M.N.S., and an Introduction by Colonel Sir T. Crisp English, K.C.M.G., F.R.C.S., A.M.S., Consulting Surgeon to the British Forces in Italy. Cloth. Price, \$9. Pp. 623, with 373 illustrations. New York: William Wood & Co., 1919.

This is a brief description of the treatment of the wounded from the onset to the time they leave the base hospital. There are lengthy chapters on the bacteriology and pathology of war wounds and the newer methods of treatment, especially those developed by the British. There are several chapters devoted to regional surgery. General anesthesia is advocated for all head operations, instead of local anesthesia as introduced by Gray and extensively used by the British surgeons. Chest injuries were handled more conservatively than was the practice in the American service. Flap amputation is recommended in preference to the guillotine method in all cases, but the wounds are left open for delayed primary or secondary suture. Numerous photographic and roentgenographic illustrations have been included.

DER KROPP DER WEISSEN RATTE. Beitrag zur vergleichenden Kropfforschung. Von Prof. Dr. Th. Langhans und Prof. Dr. C. Wegelin. Paper. Price, 14 francs. Pp. 131, with 13 illustrations. Bern: Paul Haupt, 1919.

This publication is the outcome of one part of the work of the Swiss goiter commission, which has conducted extensive investigations in the attempt to explain the high goiter rate of Switzerland. Wilms and Bircher have reported that white rats which drink "goiter water" often show goiter comparable to that of man. Langhans and Wegelin find that white rats kept in goitrous districts often show hyperplasias of the thyroid, the histologic changes of which they describe in detail; but they were unable to establish that this change depends on "goiter water" or any other single factor. They

conclude that it is best explained "through the direct action of one or several goiter poisons on the thyroid;" but they do not determine the nature of these hypothetical "goiter poisons." They do find, however, that minute doses of iodids protect the rats from goiter.

Medicolegal

Legal Quarantine of Diseased Prostitute

(*Ex parte Brooks* (Texas), 212 S. W. R. 956)

The Court of Criminal Appeals of Texas dismisses a writ of habeas corpus, and remands to custody the relator, who sought to secure her release from custody under an order issued by the director of sanitation in the United States Public Health Service who was also the chief health officer of the city of Houston, which order stated that the relator had been examined and was infected with syphilis and was ordered into quarantine at the municipal farm, there to be detained until released by order of the health officer. The court holds wholly unsupported and negated by the facts the contention that the health officer had no right or power to act in the premises because he held two offices in derogation of the provisions of the state constitution. Nor was there anything suggested by the statement of facts which supported the contention that the farm was not a suitable place for such patients, was too remote from the city and transportation and the friends of the relator. Nor was anything presented for decision by the contention that there had been numerous tests given the relator since her confinement, and that some of them showed positive and some negative results. If she was free from syphilis or gonorrhea, she might present her application for a writ of habeas corpus to the local courts, and if free therefrom might be discharged. The courts will understand that the health officers have no right or power to hold in quarantine citizens who do not show the presence of some of the diseases named in Chapter 85 of the Acts of the Fourth Called Session of the Thirty-Fifth Legislature. It was claimed that the relator was denied treatment at the hands of other physicians than the city health officer, by the terms of the act; but the court finds nothing in the statute, or facts adduced and agreed to, to support such contention. The court has carefully examined all of the contentions of the relator, and holds them to be without merit.

The legislature has the power to declare that prostitution is a source of communicable diseases, and that its suppression is a public health measure, and to direct, by enactment, that reasonable steps be taken, in the manner, and with the latitude necessarily accorded to the enforcement of sanitary and health statutes, to suppress it. The discovery in patients of the diseases at which the provisions of Chapter 85 are directed is confided to the medical profession, and the care and treatment is of necessity in the hands of the members of the same noble fraternity. There is nothing in the act which prevents or forbids any suspect, or persons detained, from perfect freedom of treatment by any reputable physician while in the custody of the officials charged with the enforcement of the law; and nothing which deprives any persons so confined for treatment of a speedy hearing at the hands of the court if there is oppression or detention without cause. The object of the law is not punishment for the unfortunates who are afflicted with these maladies, so easily transmitted and so fearful in results, but the well-being of these and the remainder of the people.

In this case the relator was shown to be a married woman, with a hard-working husband and four children, the youngest being 18 months old; but she declined to live with them, stating that she preferred the life of the streets. Testimony was adduced showing numerous bestowals of carnal favors on soldiers and other persons, and also that the relator was afflicted with gonorrhea and syphilis. The court thinks the provision of the act that such patients should be confined

for treatment until declared cured by official pronouncement is not unreasonable, unjust or arbitrary. The court's attention was not called to any authorities holding this or other similar acts violative of any of the provisions of the state constitution, or discriminatory, arbitrary or unreasonable.

Communications Privileged and Not Privileged

(*Arnold v. Ft. Dodge, D. M. & S. R. Co. (Iowa), 173 N. W. R. 252*)

The Supreme Court of Iowa, in this personal injury case, holds that, where the defendant examined as a witness a physician who had aided another physician in the treatment of the plaintiff at the hospital immediately after his injury, questions which the defendant propounded to the witness as to what the plaintiff had told him as to the circumstances of the accident were properly excluded, on the ground of privilege under the statute, the physician being deemed to occupy at the time the relation of physician to the plaintiff as his patient. Nor was the privilege waived by the plaintiff by his testimony on cross-examination. Testimony thus given by the plaintiff on cross-examination is not deemed voluntary, and is therefore not a waiver. But it was different when inquiry was made of the witness as to conversations had with the plaintiff after the professional relation had ceased. Objection was made to this line of examination on the same ground as before, and this objection was also sustained. But the latter ruling cannot be approved. The defendant had a right to inquire into conversations had after the termination of the professional relation. These in the statutory sense were not confidential. The record, however, did not disclose in any way what the testimony of the witness would have been if the questions had been permitted; and the error therefore was not a reversible one.

Not Required to Keep Copy of Prescription

(*Friedman v. State (Tenn.), 213 S. W. R. 418*)

The Supreme Court of Tennessee reverses and dismisses this case in which defendant Friedman was convicted for the reason that he "did unlawfully distribute and dispense and prescribe morphin, without keeping a duplicate of the prescription as prescribed by law." The court says that he was not a salesman of the drug mentioned, but was a practicing physician. He prescribed morphin for a habitual user, after attending the patient, but kept no copy or duplicate of the prescription. A question to be decided was whether Acts 1913 (1st Ex. Sess.) Chapter 11, required him to do so. That portion of the act bearing on this subject reads:

"Physicians who shall dispense or distribute any of the aforesaid drugs provided by this act shall keep a duplicate of all prescriptions issued by them for a term of two years, and said duplicate shall be subject to inspection by any of the officers named in the preceding paragraph." Section 2.

It will be observed that it is not all physicians who are included within the provisions of this act. It is only physicians "who shall dispense or distribute any of the aforesaid drugs provided by this act, who shall keep a duplicate of all prescriptions issued by them for a term of two years." The act thus limits the number of physicians included within its terms. It is plain and unambiguous, and there is no room for construction. Therefore the court holds that the defendant did not violate this section of the act when he failed to keep a duplicate of the prescription, because he did not dispense or distribute the drug. The court is unable to comprehend how the defendant could be deemed a dispenser or distributor of the drug merely because he failed to preserve a duplicate of his prescription. The offense was not for issuing the prescription, because the defendant complied with every requirement of the law in that respect. The offense charged was failure on his part to keep a duplicate of the prescription, which he was not required to do under a proper construction of the act.

Counsel for the state ingeniously argued that the statute should be given the construction insisted on for the state, because of supposed conveniences to the agents of the state

who check up the sale of habit forming drugs. The court may well admit the conveniences suggested, but a sufficient answer in law is that the statute does not include them. Therefore it could not matter in this case what meaning was to be attributed to the words "dispense" and "distribute," because the defendant was in no sense a party to a dispensation or distribution of the drug because he failed to keep a duplicate of his prescription. It was the prescription furnished the druggist on which he acted, and not a duplicate in the hands of a physician.

The case of *Hyde v. State*, 131 Tenn. 208, 174 S. W. 1127, is in no sense in conflict with this opinion. In that case Dr. Hyde issued a prescription without attending the patient. It was held that the prescription made him an aider and abettor in the sale, although the alleged patient was not in existence.

Requirements in Action for Malicious Prosecution of Lunacy Proceeding

(*Barton v. Woodward et al. (Idaho), 182 Pac. R. 916*)

The Supreme Court of Idaho, in reversing a judgment that was rendered in favor of the plaintiff and in directing that a new trial be granted, in this action brought to recover damages for the alleged malicious prosecution of a lunacy proceeding, holds, to begin with, that such an action is not barred by the Idaho statute which limits to two years the time within which actions may be brought to recover damages for an injury to the person, or for libel, slander, assault, false imprisonment, etc. Then, taking up the contention that such an action would lie only where there had been a malicious prosecution of a criminal or civil action, the court says that, while there are authorities which go to the extent of so holding, the modern and better rule is to the effect that an action for malicious prosecution will lie against one who has maliciously and without probable cause instituted lunacy proceedings against another. But in a trial on the merits in a civil or criminal case, or in a lunacy proceeding, the question of probable cause is not passed on by the court, judge or jury; nor is it the criterion of the decision or verdict. The decision is on the merits and, if the defendant wins, it simply means that the plaintiff has not proved his case by the preponderance of the evidence or beyond a reasonable doubt. Therefore the verdict or decision has no logical bearing on the question of probable cause, and is not even admissible in evidence on that issue.

In this case it was shown that, prior to the making of the accusation, two reputable physicians, who had attended the plaintiff and thus had had recent opportunity to examine him and to judge of his mental condition, told one of the defendants, and he told the other, that the plaintiff was insane. It was also shown that, on an occasion when the plaintiff was before the Idaho state medical board, an applicant for a license to practice medicine and surgery, his conduct was such as to excite the suspicion of those who observed it, including one of the defendants, as to his mental balance; also, that shortly prior to his arrest on the insanity charge it came to the knowledge of the defendants that he had written prescriptions which were referred to in the record as "freakish," one of which was for strychnin in doses which, had one of them been taken by the patient for whom it was intended, would have proved fatal; another was for an eye wash which, had it been applied, would have ruined or destroyed the eyesight. On the lunacy hearing, the commission of physicians appointed to examine him reported that he was suffering from paranoia, but recommended that he be not restrained. The court concludes that the plaintiff did not sustain the burden of proof incumbent on him, and that no court or jury could reasonably find from the evidence that, in making the lunacy accusation against him, the defendants acted without probable cause. It was true that there was evidence which would justify a finding of malice, but want of probable cause cannot be inferred from malice.

The certificates of admission to practice medicine in other states, offered by the plaintiff and admitted in evidence by the trial court over the defendants' objection, were not admissible in the absence of evidence tending to show his

intention to engage in the practice there. They did not prove a right of the plaintiff to practice medicine in Idaho. They were not legitimate evidence of damage to his business; nor were they any evidence of damage to his reputation or his feelings. While not legally relevant or material, they were exceedingly prejudicial. They served to inject into the case a question of whether the refusal of the medical board to admit the plaintiff to practice in Idaho was right or wrong and prejudiced the defendants, as one of them was a member of the medical board and also filed a complaint against the plaintiff for practicing medicine without a license, acting under the orders of the medical board.

Not only does the court find no proof of want of probable cause in the evidence submitted by the plaintiff, but it holds that the defendants' motion for a nonsuit should have been sustained, though, since they did not rest on the motion, but introduced evidence, it was waived. And, since the defendants did not ask for a directed verdict at the close of the evidence, it was not incumbent on the supreme court to dispose finally of the case on this appeal. Costs were awarded to the defendants.

*Relative Importance of Milk Infection in Transmission of Certain Communicable Diseases of Man. E. K. Kelley and S. H. Osborn, Boston.—p. 66.

Importance of Milk Infection in Disease Transmission.—These studies are based on investigations by the district health office of the Massachusetts State Department of Health from 1915 to 1918, inclusive. Many of the conclusions tentatively formulated in a study by one of the authors (Kelley) three years ago are strengthened by this study, based on more complete epidemiologic data. It is believed that when the total aggregate of cases reported is considered, milk, while a dangerous factor and one of potential significance, does not assume any great quantitative factor as a channel of infection, provided prompt investigations are instituted as a routine procedure of all cases occurring on milk producing and milk handling premises. Milk, as a source of diphtheria, is practically negligible. Scarlet fever, though much more frequently transmitted by milk than is diphtheria, is milk borne in only a very small percentage of instances, as compared with other sources of infection. Milk

borne typhoid is a more serious epidemiologic problem, 496 cases out of a total of 6,331 typhoid cases being attributed to this cause, or 7.7 per cent. Increased pasteurization ought to greatly decrease the percentage of frequency of milk borne cases. Although pasteurization plants have greatly increased in Massachusetts during the past four years, the relative proportion of total cases traced to milk, compared to the total cases reported, has remained about the same.

Institutional Control of Diphtheria. F. A. Finnegan, Boston.—p. 93.
*Two Cases of Fetal Asphyxia. C. J. Kickham, Boston.—p. 94.

Blood Plasma Chlorids versus Renal Function.—The blood plasma chlorids were determined by Rappelye in 104 patients showing no obvious evidence of compromising physical disease, the blood being drawn twelve hours after the preceding meal. No relationship could be established between the chlorid values and the blood urea nitrogen, rate of elimination of phenolsulphonaphthalein, blood pressure readings or urine specific gravity. A small group of cases of so-called essential vascular hypertension seemed to show an elevated renal threshold for sodium chlorid. Attempts to lower the threshold have given no conclusive results.

Fetal Asphyxia.—In one of the cases reported by Kickham, the patient was on her way to the bathroom when she "felt something." This proved to be the new-born child, but the head had remained in the vagina. The infant was in a state of pallid asphyxia but with the fetal heart still audible. Efforts at resuscitation proved futile. The child died without breathing. In the second case, the woman had a precipitate birth of twins, having had only one sharp pain. One fetus was still within its amniotic sac, which had not ruptured, although the entire sac was outside of the vulva. The sac was ruptured at once, attempts were made to resuscitate the baby, but it died without breathing.

*Splenic Anemia in Children. J. W. Ames, Denver.—p. 12.

Splenic Anemia in Children.—A case of Banti's disease is reported by Ames, occurring in a boy, aged 6 years. A splenectomy was done and the boy recovered. He has gained 20 pounds in weight, eats and sleeps well, and gives every promise of living out the natural span of life. An interesting feature in the case was the fact that the boy's mother, who was only 16 years of age when he was born, gave a clear history of an obscure disease, accompanied by pronounced anemia from her birth to her twelfth year. She was transfused from the husband at the time of the boy's birth for a puerperal hemorrhage without benefit.

*Rational Therapeutics of Exophthalmic Goiter. I. Bram, Philadelphia.—p. 467.

*Hypophysial Diabetes. J. Koopman, The Hague, Holland.—p. 485.

Rôle of Pineal Gland in Pediatrics.—A review of the literature has convinced Gordon that it is exceedingly difficult to arrive at any conclusive opinion as to the functional activity of the pineal gland. There has been nothing substantial brought forward to show that it possesses an internal secretion. The experimental work has failed to prove that it possesses a function, and no experimental studies are so complete as to allow comparison with the very striking syndrome seen clinically. If the views of Horrax and others that the pineal gland controls the inhibition of sex growth were true, then pineal feeding should postpone adolescence, but observations by Dana and Berkeley and by McCord produced the opposite. On the other hand, if the feeding results of McCord are correct, then the extirpations of Dandy and Horrax ought to have brought overwhelming evidence of a pineal function. In the final analysis, Gordon says, it seems justifiable at the present time to state that our knowledge of the function of the pineal is more problematic than accurate.

Rational Therapeutics of Exophthalmic Goiter.—Bram claims that careful nonsurgical management is capable of completely and permanently curing the great majority of cases of hyperthyroidism. The occasional exception not responding to nonsurgical measures is not an instance of genuine exophthalmic goiter but is one of malignant degeneration of the thyroid gland, a case of toxic symptoms superimposed on a long standing nontoxic goiter, or a case brought to the clinician's attention in a moribund condition. Bram, in unison with others interested in thyroid therapy, does not hesitate to conclude that he has been able to cure every case of primary exophthalmic goiter in which a fair degree of cooperation was obtainable; this was accomplished in from six months to two years, depending on the exigencies of the case treated. Strict individualization of the case in hand is the dominating principle of treatment. The proper medical attendant, the proper social atmosphere, and the right kind of dietetic, hygienic, medicinal, psychotherapeutic, electrotherapeutic and other measures properly applied for the required length of time should yield a permanent cure.

Hypophysial Diabetes.—While proof is lacking that the two cases reported by Koopman are cases of hypophysial diabetes, he believes it is probable that the hypophysis played an important part in them, as good results were obtained from the administration of hypophysis extract. Three times daily, a tablet corresponding to one tenth of the fresh gland of the cow was given. The effect was striking. The third day of the onset of the treatment 200 gm. of bread and 50 gm. of meat were tolerated without glycosuria. The fourth day 100 gm. meat and 200 gm. bread gave rise to a glycosuria of 16.4 gm. After a fortnight the protein tolerance was 200 gm. of meat. It has not been possible to increase this.

Surgical Treatment of Enuresis in Adult Female.—In one case, cited by Schurmeier, that of a young woman, aged 21 years, he performed the simple operation of freeing the urethra through the tunica propria, approximately five-eighths inch deep, gave the meatus urinarius one half turn and sutured with interrupted fine silkworm. Four hours after the operation, the patient was catheterized and every eight hours afterward, for four days. She was now able to void urine with but slight discomfort. The urine was kept bland. She left the hospital at the end of two weeks with fairly good control over the urinary mechanism. Nine months passed, and the patient was greatly encouraged and anxious to have a second operation, which was calculated to make the surgical procedure 100 per cent. successful. Schurmeier performed the second operation. The urethra was freed as in the previous operation, a three-fourths turn was made and it was stitched as far back as possible, in the new position the urethra now had. The external closure was made as in the previous operation. The patient was catheterized four hours later, and every six hours thereafter for a few days; then the intervals were lengthened, until on the sixth day the patient was able to urinate in the normal way. After two weeks the patient left the hospital. She had good control over the urinary mechanism more than four years after the operation.

Use of Pure Cocain for Nasal Anesthesia.—The method Andrews has adopted is as follows: First, apply to the part to be anesthetized pencils of cotton saturated with from 1:1,000 to 1:5,000 solution of epinephrin. These pencils should be left in position for from five to eight minutes. After their removal, a small pledget of cotton is wound on an applicator and dipped in water or epinephrin solution. The excess of fluid is removed from the pledget by touching it to a towel. The damp pledget is then dipped into the powdered or flake cocain, and a small amount of the cocain is rubbed gently over the desired area. Removal of the excess of fluid from the pledget is important, for if the pledget is too wet, the fluid will run off into the remaining dry cocain and cause it to crystallize. If profound anesthesia is to be produced, a second application can be made after two or three minutes. Ordinarily, anesthesia is sufficient for examination or operation to be commenced immediately after the second application. The advantages claimed for the method are: It is safer than cocain solutions. The contracting effect of the cocain powder on the blood vessels seems to prevent its absorption. The anesthesia is more prompt, more profound, and more lasting. The small amount of cocain required is advantageous both from the standpoint of safety and economy. From one-fourth to one-half grain of flake cocain is sufficient to anesthetize both side of the septum for a submucous resection.

- Laboratory Service of Divisional Laboratories. L. A. Fritze.—p. 16.

Chronic Nephritis in the Young.—The ages represented by Biering's cases are 11, 15, 18 and 23 years, respectively. The onset in each instance was gradual and insidious; the distinctive subjective symptoms were severe headache, nausea, vomiting, polyuria, loss of weight and strength; albuminuria with casts, in a urine of low specific gravity; cardiac hypertrophy and arterial hypertension prevailed as the clinical signs. In the oldest patient a marked peripheral arteriosclerosis was present. A preceding acute nephritis could not be established in any of the cases. The familial tendency was noted in three cases. In one case the father died at 33 years of age of a sudden death simulating apoplexy, in a second case the mother died at 32 years of age of nephritis, and in the third case examination of an aunt of the patient, 31 years of age, and an uncle, 40 years of age,

revealed a condition of chronic nephritis with hypertension, death occurring in each instance from cerebral hemorrhage. Only two of the four patients remained under observation long enough to permit instituting any definite plan of treatment. Active eliminative measures, rest, restrictions in diet, with vasomotor relaxants, produced some improvement in symptoms, but apparently did not influence the course of the disease or avert the fatal outcome. Necropsies were not permitted.

Destroying Lice in Clothing.—The observations reported by Hutchison show that if the penetration of steam is sufficient to produce a temperature of 75 C. (167 F.) in the center of a barracks bag (or other load of infected goods) all eggs and active stages of body lice will be destroyed. If the disinfectors are operated efficiently on the time schedule now employed (viz., a 10 inch preliminary vacuum; 15 pounds steam pressure for fifteen minutes, reckoned from the time the steam is turned on; followed by a 10 inch drying vacuum), the requisite temperature (75 C.) is attained in every case. By efficient operation is meant (1) the maintenance of a full head of steam so that the 15 pounds pressure in the disinfecter is produced within five minutes, thus allowing at least ten minutes for exposure; (2) overloading must be guarded against; (3) the individual bundles must not be rolled too tightly. Little, if any, shrinkage of woolen goods is caused by this treatment. There is, of course, some wrinkling, but these wrinkles are not permanent and may be remedied by pressing.

Mouse Oxyurid in Man.—The parasite described by Riley was found in the feces of an American-Bohemian child living in Zamboanga. She was one of a family of five, all of whom were heavily infested by the worm in question. From the available data, it was evident that the food of the child and of others of the family had been grossly contaminated by mice or rats. This accounts for the infestation by one of the commonest nematode parasites of these rodents. Incidentally, it furnishes circumstantial evidence in favor of the view that *Hymenolepis nana* of man and *Hymenolepis murina* of rodents are one and the same species, as has been claimed, on morphologic grounds, by various investigators.

Nonspecific Immunity.—Is there any scientific evidence of the possibility of the development of a nonspecific bacterial immunity, or increased resistance to infection, is the question discussed by Vaughan and Palmer. The basis of their remarks is, in the main, the work done by the late Victor C. Vaughan, Jr., and first reported as early as 1905. The authors believe that it is an established fact that an increased tolerance to the protein poison can be established, that it is nonspecific and that no antibody is generated. Further, it is evident that a nonspecific bacterial immunity, never reaching a degree comparable with that attainable in toxic immunity, but certainly affording protection beyond that usually present, is secured by repeated introduction of the protein poison into the body. Vaughan and Palmer do not believe that this nonspecific immunity prevents infection with a newly imported virus, but that it mitigates the effects of this infection in some instances so markedly that no symptoms are recognizable, while in others its effects are shown only in the lower death rates among those possessing it. Animal experiments have shown that nonspecific immunity is of low grade. It protects quite securely against the minimum lethal dose of the culture, rarely against twice this amount, but beyond this it usually fails. However, this specific immunity, which the nonspecific form has enabled the individual to attain, may protect against from eight to twelve times the minimum lethal dose.

Surgical Treatment of Exophthalmic Goiter.—The conclusions presented by Crile as to the surgical treatment of exophthalmic goiter are based on his personal experience in 2,250 thyroidectomies of which 1,169 were for exophthalmic goiter; of the latter, 660 cases, or 56 per cent. were ligated. No patient was rejected for operation unless he or she was in the state of dissolution. In the last series of 331 thyroidectomies, 116, or 35 per cent. were first ligated, and no case was rejected. Among the 116 ligations there was only one death. The patient was in the early stage of dissolution and was delirious when the ligation was made. The downward course of this case was not arrested. The series of 1,169 thyroidectomies for exophthalmic goiter began with operations under ether alone, and with no special precautions. The mortality rate in these early cases was 16 per cent. After the adoption of anociation-nitrous oxid-oxygen and local anesthesia with the anesthetization of the patient in his room—the mortality rate fluctuated between 2 and 5 per cent, until by the adoption of a new system of management the mortality rate for all goiters among the last 331 thyroidectomies dropped to 0.6 per cent. This number includes one series of 206 consecutive thyroidectomies without a fatality and 182 thyroidectomies for exophthalmic goiter with two fatalities, a mortality rate of 1.1 per cent. The new system of management consisted of the adoption of nitrous oxid-oxygen, the use of local anesthesia, the multiple stage operation, the exclusion of the psychic factor, and the application of the principle of carrying the operation to the patient. The operative procedures are graded according to the severity of the disease. In moderate cases the entire operation may be completed at one seance. In

more severe cases the thyroid activity is diminished by preliminary ligation with the patient in bed, under nitrous oxid-oxygen analgesia and local anesthesia. In extremely grave cases it may be necessary to diminish the thyroid activity by multiple steps—ligation of one vessel; ligation of the second vessel; partial lobectomy; complete lobectomy—allowing intervals of a month or more between these stages, the length of each interval being determined by the degree of physiologic adjustment. If, during the operation, the pulse runs up beyond the safety point, the operation is halted, the wound dressed with flavine, and the operation completed after a day or two when conditions have again become safe. In some cases, even though the thyroid has been resected, it is advisable to dress the unsutured wound with flavine and make a delayed suture in bed the following day under analgesia. In certain cases lobectomy is performed while the patient is in bed and under nitrous oxid analgesia and local anesthesia. Crile insists that psychic control of the patient on the part of the surgeon, the intern, the anesthetist, and the nurse is required throughout to diminish the intense drive. An associated regimen should be prescribed for the preoperative, interoperative and post-operative periods. The preoperative and the postoperative management are of almost equal importance to that of the operation itself. If, after the operation, the temperature becomes excessively high, with greatly increased pulse and respiration, the patient is packed promptly in ice. To avoid the effects of too sudden a withdrawal of thyroid secretion, thyroid extract is given the night before a lobectomy.

Peripheral Nerve Injuries.—The principles which governed Frazier and Silbert in dealing with their cases are summarized as follows: Liberation or neurolysis has been given preference in the absence of a complete anatomic division or a neuroma in continuity when after excising all scar tissue and laying bare the nerve sheath there is a quick response to faradism. Resection and suture are essential whenever neurolysis is contraindicated. Resection must be carried centrad and distad until healthy scar-free fasciculi are exposed. In bridging defects, the nerve transplant must not be employed until advantage has been taken of every other reasonable measure: to wit, nerve stretching, immediate or continued (as with sutures through bulbs), mobilization, transposition as of ulnar and musculospiral nerves, and, in exceptional instances, lateral implantation suture, such as implanting the ulnar or musculospiral nerves into the median. When these fail, a nerve transplant is justifiable, the autotransplant being the first choice, and homotransplant (preserved in liquid petrolatum, or 50 per cent. alcohol) the second choice. For autotransplant, the musculocutaneous or sural nerves of the leg, the radial or internal cutaneous nerves of the arm, may be selected on the basis of convenience. In nerve suture it is equally important to know what one ought not to do. In this category we include suture at a distance, the flap operation, bilateral anastomosis (as recommended by Hofmeister), and tubulization. Sharp, clean dissection, careful hemostasis, the approximation of healthy fasciculi, without undue tension, represent the tripod on which the success of nerve suture rests. Tendon transplantation should be employed when suture fails and is particularly appropriate in residual palsies of the posterior interosseous, with inability to extend wrist or fingers, and anterior tibial palsies with resulting foot drop. The after-treatment should include (a) enforced fixation for a period of from four to six weeks with gradual straightening of the limb, (b) massage and galvanism until voluntary movement returns, (c) exercises varied according to the muscles involved and with a view of sustaining the interest of the patient.

Chronic Trigonitis in Female.—Lindeman reports the favorable results he has obtained from the injection of 2 per cent. quinin and urea hydrochlorid in the treatment of these cases.

Recurrent Hernia after Gastro-Enterostomy.—In the case reported by Bryan there was a hernia of the jejunum posterior to the gastrojejunostomy. At operation the intestines were simply pulled back.

Methylene Blue in Diagnosis of Gastric Ulcer.—Baker reports four cases in which he gave the patient 3 grains of methylene blue, dissolved in an ounce of water, for the purpose of making easier the location of the ulcer. In all ten cases have been observed where methylene blue has been used.

Rupture of Uterus; Peritoneal Encystment.—The interesting features of Blakely's case are numerous attempts (7) to produce abortion; a traumatic rupture of the uterus with extrusion of a four months' fetus into the general peritoneal cavity followed by general peritonitis; recovery from the peritoneal infection, healing of the uterine tear, encysting of fetus, formation of a vaginal fistula; removal of a large portion of the fetal skeleton with indistinguishable soft parts five months later through the vagina; ultimate recovery.

Restoration of Bile Passages.—In a case of complete obstruction of the common bile duct, Collins dissected out the tract of the fistula through the abdominal wall to the skin which remained from a previous operation. This fistulous tract became a well organized tube of connective tissue about one-quarter inch in diameter. A section of a No. 12 French soft rubber catheter was inserted into the open end of the fistulous tube for a distance of 2 inches. This was secured with one catgut stitch. Four inches of the rubber tube projected beyond the end of the fistulous tube. At a point opposite the margin of the liver a stab wound was made into the duodenum. The fistulous tube with the rubber tube projecting from its distal end was turned into the lumen of the intestine and the stab wound was closed with a pursestring suture. The intestine was then drawn up and sutured after the manner of the Witzel operation. The anastomosis was further strengthened by suturing over it a tag of omentum. The abdominal wound was closed without drainage. Recovery was quick and uneventful. The rubber tube was passed on the sixteenth day. A search through the literature disclosed only two cases where this method of repair was adopted, and both were unsuccessful.

Clinical Types of Abdominal Tuberculosis.—Monsarrat discusses tuberculosis of the ileum, cecum and rectum, and cites cases to illustrate the methods of treatment. He says that when tuberculous disease, either of the ileum or large bowel, is associated with definite intestinal obstruction, operation is always necessary, and the choice lies between exclusion by anastomosis and excision. If the obstruction is acute, exclusion by anastomosis is to be preferred; if the obstruction is subacute the exact local condition must decide. A mass that is easily isolated is better removed. When such tuberculous bowel lesions are not associated with obstruction, or with an obstruction that is chronic and capable of relief by aperient, the advisability of operation will depend

on whether the bowel disease is or is not the sole demonstrable lesion in the body. If the lung is also affected it will probably be wiser to decide against operation. With regard to disease of the rectum, he knows of no actual evidence that a remedy is to be found in the establishment of an artificial anus. In one instance, this procedure added to the patient's discomfort without obvious benefit to the rectal condition. When the rectum is affected above the peritoneal reflection, and is associated with abscess, evacuation of the abscess by the intraperitoneal route is to be recommended, but except for the treatment of this complication, operation has no service to offer. Lastly, in selected cases, operation gives good results in limited tuberculous disease of the mesenteric lymph nodes. According to the extent and stage of the focus, this will take the form either of enucleation or of excision of the mesentery involved, together with the associated portion of intestine.

Intestinal Protozoa in Troops in Mesopotamia.—The total number of persons examined by Boulenger was 1,378. The cases consisted of acute dysenteries (i. e., with blood and mucus in the stools), colitis and diarrhea, as well as a number of convalescents passing more or less normal stools. The following parasites were found: *Endameba dysenterica* was found in 201 cases; *Endameba coli* in 264 cases; *Giardia (Lamblia) intestinalis* in 133 cases; *Trichomonas intestinalis* in 111 cases; *Chilomastix (tetramitus) mesnili* in sixty-eight cases; and *Coccidun (isospora)* in eight cases. Only one outbreak of bilharziosis occurred among the troops in Mesopotamia up to August, 1918, seventy-one of the Indian personnel of a general hospital having become infected with *Schistosoma hematobium*. The results of an investigation of the Arab population of Mesopotamia showed that the disease was common throughout the country, both in the Tigris and the Euphrates districts: the average infection by *Schistosoma hematobium* was approximately 20 per cent. of the male Arabs examined. The mollusk *Bullinus contortus*, known to be the second host of the parasite in Egypt, was found in Mesopotamia, but does not seem to be of common occurrence in that country.

Coma as Cause of Death in Diabetes.—An analysis of the blood was made by McCay in practically all cases of diabetes, with or without albuminuria, all cases of kidney diseases with or without uremia, and also in a large number of perfectly normal individuals. The absence of any well marked signs of acidosis, either during the course and treatment of diabetes, or even in the terminal coma, raised the authors' suspicions that the coma, as a terminal phenomenon in the type of diabetes prevalent in India, was not identical with diabetic comas as seen in Europe. Other considerations pointed to the probability of the coma being uremic. He could find no essential difference between the chemical condition of the blood in patients with uremia and in patients dying in coma who had been suffering from diabetes, except for the presence of hyperglycemia in the latter, and this, he

says, can hardly be regarded as a cause of coma. Again, the outstanding feature of these dying diabetics was the great increase in the nonprotein nitrogen of the blood. Acetone, urea, phosphates, etc., may be increased to a greater or less extent, but the signs of acidosis are far too slight to enable one to ascribe the coma to any ill effects caused by a meager retention of acetone bodies in the blood. McCay, therefore, arrives at the conclusion that the functional derangement of the kidney that accompanies diabetes is the all important factor in producing the necessary conditions of the blood that lead to coma and death.

Treatment of Diabetes in India.—The treatment of diabetes in India, McCay says, resolves itself into the treatment of diabetes levis, or the milder forms of the disease met with in European countries. On the whole, it is even a less serious and less fatal condition than the ordinary diabetes levis of Europe as it does not present the same tendency to progress or to become complicated with severe acidosis and diabetic coma. McCay has not met with a single case, among the hundreds treated or seen by him, in which proper dietetic measures failed to clear the urine of sugar and keep it clear.

Pathology of Experimental Rabies.—Owing to the growth of the rabies organism in the central nervous system, Cornwall claims that irritative stimuli pass along the splanchnic nerves to the suprarenals and liver and give rise to the discharge into the blood stream of an excess of sugar. There may or may not be an accompanying excessive secretion of epinephrin. Much damage is caused both to the kidneys and to the suprarenals by toxic agents in the blood derived from the growth of the rabies organism in the central nervous system.

Pharmacodynamics of Quinin.—Cornwall presents evidence that quinin administered to healthy rabbits intravenously and intramuscularly over a period of eight or nine months causes damage to the cellular elements of the suprarenals and kidneys. There is also evidence that the rate of disintegration of red blood cells in the spleen is increased.

Pathogenesis of Deficiency Disease.—Diets deficient in accessory food factors McCarrison found give rise in pigeons and in guinea-pigs to congestive and atrophic changes in all coats of the bowel, to lesions of its neuromuscular mechanism, to impairment of its digestive and assimilative functions, and to failure of its protective resources against infection. The functional perfection of the gastro-intestinal tract is dependent in considerable measure on the adequate provision of accessory food factors derived from fresh fruit and vegetables. Certain gastro-intestinal disorders in the human subject—of which three examples are referred to—may owe their origin to the long continued subminimal supply of accessory food factors.

Influence of Scurvy Diet on Suprarenals.—According to McCarrison, a scorbutic diet gives rise in guinea-pig to (1) an increase in size and in weight of the suprarenals; (2) a marked diminution in the epinephrin content of these organs; (3) hemorrhagic infiltration of the suprarenals, usually circumscribed in extent and situated around the periphery of the suprarenal cortex; and to (4) degenerative changes in the cellular elements of the suprarenal cortex and medulla. The impairment of suprarenal function occurs before clinical evidences of scurvy manifest themselves.

Hoffmann Bacillus and Diphtheria in India.—The bacillus of Hoffmann was found by Knowles in 30 per cent. of cases of diphtheria; in 11 per cent. of diphtheria carriers, showing the true Klebs-Loeffler bacillus; in only 0.4 per cent. of healthy throats among European children during an epidemic; and in only 5 per cent. of the throats of 103 Indians in the absence of any epidemic. The bacillus of Hoffmann was met with (a) before, (b) with and (c) after the presence of the true Klebs-Loeffler bacillus in the same throat. While the two organisms appear to be entirely different as regards morphology, cultural reactions and pathogenicity to animals, yet it is suggested by Knowles that there is a symbiotic relationship between them that the rarity of the bacillus of Hoffmann in India may be associated with the

relative rarity of diphtheria in epidemic form. Reverse conditions hold in temperate climates.

Cultivation of Gonococcus.—Maitra claims that the gonococcus is best cultivated under reduced oxygen tension. Primary cultures grow equally well on Loeffler's blood serum or urine agar with egg yolk provided a fair amount of purulent exudate is used. Subcultures grow better on Loeffler's blood serum. Bacterial yield can be augmented by adding fresh serum, preferably human serum. Human serum, heated to destroy its bactericidal properties, gives no advantage over fresh serum in promoting growth of gonococcus: probably the vitamin content is destroyed to some extent by heating.

Acid-Fast Bacilli in Blood of Lepers.—Acid-fast bacilli, agreeing morphologically with the leprosy bacillus, were demonstrated by Iyengar in a considerable proportion (7) of blood films made from forty lepers. The presumption is that these are present in the blood itself, although there remains the possibility of their having been derived in the process of venipuncture. The skin, however, at the site of puncture showed no sign of leprosy affection. The possibility of the presence of acid-fast bacilli in the reagents used has been excluded by the use of the blood of healthy persons as controls. Iyengar suggests that examination of the blood may be used with advantage as a routine method of diagnosis in cases of suspected leprosy. It is possible that this examination may sometimes afford evidence of the affection when the ordinary method of examination has failed.

*Goiter and Psychoses. N. R. Phillips.—p. 235
*Cytology of Cerebrospinal Fluid in Mental Disease. G. L. Brunton.—p. 249.

Goiter and Psychoses.—That the rôle played by goiter in the psychoses is more extended than is indicated, is the theme of Phillips' paper. Of 200 patients examined by him, the actual proportion of goiter was 12 per cent. No less than seventeen of these patients suffered from manic-depressive insanity or from the melancholia of involution, i. e., 70 per cent. of the whole number. Of the remaining seven, four were cases of dementia praecox and three were cases of paranoia. Phillips believes that those cases show that the nature of the psychosis is, in some degree, determined by the form of the functional disturbance of the thyroid gland, e. g., hyperthyroidism is usually associated with states of excitement, agitation, etc. (manic-depressive insanity), whereas hypothyroidism is more often associated with states of apathy and indifference (dementia praecox).

Cerebrospinal Fluid in Mental Disease.—In the examination of the cerebrospinal fluid as an aid in the diagnosis of mental disease, Brunton finds that Alzheimer's method is the best for the cytologic examination. The cells of the great-

est diagnostic importance are the plasma cell, the phagocytic and the endothelial cell, and the lymphocyte in excess. A high cell count, with an excess of lymphocytes together with the presence of plasma cells, is strong evidence of a parasymphilitic lesion.

Standardizing Serum Diagnosis of Syphilis.—The method suggested by Lewis for the standardization of red blood cells and complement is as follows: The blood is collected, defibrinated, washed and deposited in the usual manner. The deposited red cells are then mixed with three or four times their volume of physiologic sodium chlorid solution. A 25 or 50 gm. specific gravity flask is weighed accurately (a) dry and (b) filled with physiologic sodium chlorid solution. This solution is then thrown out and replaced with the heavy suspension of red cells and is reweighed. In these weighings the usual precautions are taken, such as the accurate filling of the flask, and the weights are taken at 60 F. This latter is accomplished by immersing the specific gravity bottle, solution and suspension in a water bath at 60 F. The relative weight of the red blood cell suspension against physiologic sodium chlorid solution at a constant temperature is thus calculated, and this can be utilized as a basis for the further dilution of the suspension. This method is not a true specific gravity method. Lewis has found that a relative volume weight of 1.0040 is a suitable dilution for use, and that the minimum hemolytic dose of complement based on such a suspension of red blood cells gives a good range of results in weak positive, positive and strongly positive cases.

A German Bullet Embolus.—This case is recorded by Fry as a remarkable instance of the migration of a rifle bullet in the venous blood stream. There was a small oval wound of entry one-half inch below the left anterior superior iliac spine. The bullet entered the vascular system by gouging the posterior aspect of the left external iliac artery and penetrating into the lumen of the left internal iliac vein, causing an arteriovenous aneurysm of these vessels. From this position the bullet was carried up the common iliac vein and the inferior vena cava. It passed through the chambers of the right side of the heart, through the pulmonary valve into the left branch of the pulmonary artery where it impacted as an embolus in one of the branches supplying the lower lobe of the left lung, thereby causing two infarcts in this lobe. For a week, the patient's general condition remained good. Ten days after its receipt the wound was almost healed, but gangrene of the left leg was complete and the leg was therefore amputated below the knee. Finally, the patient became delirious and he died in coma, one month after the receipt of the wound. The case is discussed in detail.

Malaria and Insanity.—Forrester states that in Macedonia malaria was reckoned as the biggest factor in the causation of mental disease among the troops. Indeed, the admission rate of the latter was almost an exact parallel of the malaria curve. Altogether, during ten months, there were 116 admissions to the mental department, each patient giving a positive malarial history. In thirty-two cases the mental symptoms were in association with an actual attack of malaria, and in eighty-seven cases the mental symptoms were the result of repeated attacks.

Improved Technic for Staining Sputum for Tubercle Bacilli.—It is claimed by Distaso that his method overcomes some of the difficulties and raises the percentage of positive results by at least 25 per cent., besides affording a film which is restful to the eye and easy of manipulation. It takes less time in execution than the ordinary method. The method allows for twice the usual amount of sputum, secures the easy solution of the tough mucopurulent pellets, and gives an even film and a very transparent counterstain. A thick portion of the sputum or several mucopurulent pellets are selected and transferred to the slide. One drop of 5 per cent. sodium hydroxid solution is added and the sputum emulsified, with the aid of heat, into a transparent gelatinous mass, which is spread evenly and set to dry in the incubator. When perfectly dry, it is immersed in fuchsin, warmed to incubator temperature, and allowed to remain in the incubator for fifteen minutes. It is then washed in equal parts of Esbach solution and water, decolorized with 25 per cent. nitric acid until faintly pink, and then washed in water, in 60 per cent. alcohol, and then again in water. The counterstain used is malachite green one part of saturated alcoholic solution in nineteen parts of water, for from thirty to sixty seconds, and the slide is rinsed and dried.

Direct Infection in Tuberculosis.—As bearing on the subject under discussion Ward cites the case of a girl, aged 20, living on an isolated farm, who developed acute tuberculosis and died within three months after the onset of the disease. Taking a history in the usual way, there did not seem to be any likelihood that she had been in contact with another case of tuberculosis, but on examining, among others, a brother, who seemed breathless, and an aunt staying in the house, who had a cough, both showed physical signs of pulmonary tuberculosis. The aunt's sputum contained tubercle bacilli; the brother refused to send his sputum away for fear the result might interfere with his dairy work. Apart from a home examination, Ward says, these two cases would never have been discovered.

Enteric Cyst Causing Intussusception.—In Bryan's case, the cyst was situated in the antimesenteric wall of the ileum close to the ileocecal valve. It filled the lumen of the intestine, two thirds being in the ileum and one third in the cecum. The intussusception occurred in the terminal portion of the ileum. Two operations were performed, owing to the condition of the patient during the first operation. This was terminated hastily with a later anastomosis between the cecum and ileum, the cyst having been punctured and emptied. At the second operation the cecum, six inches of ileum and the lateral anastomosis performed at the first operation together with the cyst, were excised and an end to end anastomosis was made between the colon and ileum. The patient, aged 6 years, made a complete recovery.

Undiagnosed Disease.—The four patients seen by White presented the same symptoms, slight elevation of tempera-

ture, never exceeding 100 F. and of only one day's duration; a rash consisting of flat circular papules, rarely vesicles or blebs, not fading entirely on pressure, the size of a pea and slightly larger, first most pronounced on the wrist and forearms and then beginning to appear on the chest, thighs and legs. Later, White saw many more such cases, from six to eighteen every day. The onset was usually sudden, with severe frontal headache, giddiness or actual fainting while on parade, the patients all being soldiers on duty in India, and members of a recently arrived English regiment. Severe pruritus was a prominent symptom in about one half the cases. White was unable to arrive at a diagnosis.

*Preferable Incisions for Laparotomies. E. Rouffart.—p. 577.

*Radium Treatment of Cancer of Uterine Cervix. P. Degrais.—p. 623.

The Laparotomy Incision.—Rouffart devotes nearly fifty pages to arguments for and against the various incisions in vogue, describing nine longitudinal or slanting incisions and three transverse methods. In his compilation of 1,506 new cases of the transverse incision, eventration developed only in 0.33 per cent. and in these cases there had been suppuration in the abdominal wall in all but one. Suture of a median longitudinal incision should always be reinforced with muscle tissue from the rectus. Other longitudinal incisions compel section of nerves to such an extent that the nutrition of the tissues is seriously compromised. All his arguments sustain the superiority of the transverse incision whenever practicable for gynecologic and obstetric laparotomies.

Radium Treatment of Cancer of Uterine Cervix.—Degrais declares that curietherapy, as he calls it, is emerging from the empiric stage. When surgery is impotent, then radium has a unique rôle, also in preparing cancers for operation and as a sequel to operation. He uses doses ranging from 27 to 200 millicuries, with filters of from $\frac{3}{10}$ mm. platinum to 1 mm. silver, with exposures of from forty-eight to seventy-two hours. He gives no figures, but adds that there is scarcely a single case in which some benefit from the radium was not apparent.

*Jaundice in Secondary Stage of Syphilis. L. Giroux.—p. 739.

Jaundice in Secondary Stage of Syphilis.—Giroux remarks that testing the fragility of the blood corpuscles explains the hemolytic origin of the jaundice, anemia and enlarged spleen, without disturbance in the general health, which are sometimes observed in the secondary phase of syphilis. The jaundice may be due to hemolysins in the blood, but in either case the disturbance is mild and subsides in a few weeks or months, as also the jaundice after arsphenamin treatment. The nature of the latter is being disputed just now, as also the indications for treatment. Some advise to suspend, others to push the arsphenamin when jaundice develops. Sicard says that an increase in the urea content of the blood under arsphenamin should warn of impending jaundice.

Signs of Latent Tracheobronchial Glandular Disease. P. F. Armand-Delelle.—p. 995.

Muscle Signs of Pulmonary Tuberculosis.—Hallbron and his co-workers examined 157 patients and fifty-two healthy controls for the abrupt local contraction of the trapezius and other muscles when the margin was suddenly pinched. This has been cited as a sign of a chronic tuberculous process in the lung on that side. The contraction across

the muscle feels like a cord, and Lévy even contends that the absence of this *corde musculaire* or myo-edema excludes tuberculosis, or at least an active process. The myotonic reaction in the trapezius occurs normally on both sides; it is significant only when it is exaggerated on one side. The reflexes on percussion of the deltoid, pectoralis and supraspinatus are more pronounced on the diseased side. These muscle signs were pronounced in from 81 to 96 per cent. of the tuberculous examined, usually the active cases. The findings were positive only in 10 per cent. of the presumably healthy controls. These muscle signs are especially useful in dubious cases, and in suggesting a tuberculous origin for emphysema and chronic bronchitis. The reaction does not always correspond to the side with the most extensive lesions, but to the most active. Sainton greases with petrolatum the thumb and forefinger for pinching the muscle, and states that the myo-edema never lasts for more than eight to twelve seconds. It occurs most pronounced and persistent in typhoid, in chronic pulmonary tuberculosis, and in lead poisoning, and is a sign of impregnation of the organism with toxins. Lion reported positive findings even with intoxication from stenosis of the pylorus.

Necropsy after Induced Pneumothorax.—Necropsy showed the complete cure of the tuberculous cavity in the lung treated by induced pneumothorax for thirty months. Death was due to intercurrent influenzal pneumonia in the other lung. Slight tuberculous lesions in the latter had healed likewise. The healed tuberculous lesions were of the torpid, cheesy type. Burnand's experience indicates that the minimum period for effectual collapse therapy in advanced cases is two or three years. He adds further that fourteen of his twenty pneumothorax patients passed unscathed through intercurrent influenza; six died.

*Mechanical Correction of Fractures. R. Bonneau.—p. 371.

Treatment of Pseudarthrosis of Forearm.—Dujarier obtained consolidation in 32 of his 36 cases of pseudarthrosis of the radius; in 16 of 19 of the ulna, and in all of the 15 cases in which both bones were involved, that is, a total of 90 per cent. successes. Sixteen illustrations show his technic. A bone and periosteum graft from the tibia was used to bridge large gaps. In 3 cases he cut the graft longer than the gap but the part that extended beyond the gap was cut thin and thus these ends embraced the stump, while the stumps rested on the thick cylinder between. In 3 cases the graft had been taken from the front of the tibia, and the tibia fractured later. He now chisels off the flap always from the internal aspect of the tibia, and sometimes cuts two flaps, a shallow and a deep one.

Correction of Displacement of Fractured Bones.—Bonneau's illustrations show his method of pulling up one stump into place with wire, and pushing the other stump down into place with a metal rod, both fastened to a standard bridging the lesion.

*Leg Sign of Pyramidal Tract Disease. J. A. Barré.—p. 793.

*Complementary Factors of Growth, Etc. R. Thiebaut.—p. 795.

Pyramidal Sign.—Barré describes a leg sign of derangement in the pyramidal tracts which is more constant and instructive, he says, than any other sign known to date. The patient lies face down on bed or table, and the legs are flexed at the knee. He is told to hold the legs in this vertical position, but he is unable to do this in case of paresis from pyramidal disturbance, and the leg gradually sinks down more or less, although the muscles of the thigh can be seen contracting in order to keep the leg upright. This "leg maneuver" is negative with paralysis of hysteric or peripheral origin, and even with cerebellar disease, if the pyramidal tracts are intact. All other signs of pyramidal lesions are indirect, but this is direct, and the disappearance of the sign in the course of paraplegia indicates the return of volitional control.

Complementary Factors of Growth.—Thiébaud applies this term to what Collum and Davis call the secondary factors of growth and balance, and theorizes that they are indispensable to the action of diastases. The latter depends on the special distribution of the electrons on the surface of the colloidal substances. When the complementary factors are lacking, the molecular constitution of the colloidal mediums in which the diastases work becomes so modified that the diastases are unable to perform their specific function.

Cure of Tetanus under Chloral and Sodium Persulphate. T. Reh.—p. 337.

Sterilization by Roentgen Exposures of the Ovaries.—Guillermin declares that exposures to the roentgen rays form the simplest and least harmful means for arresting ovarian functioning in women with pulmonary tuberculosis. Even menstruation may have a decidedly unfavorable action on tuberculosis, inducing congestion and whipping up hemoptysis, so that there is every reason to suspend the functioning of the ovaries in such cases, to say nothing of the menace from a pregnancy. Bezançon long ago called attention to "these tuberculous women killed by their menstrual periods." In two cases he suppressed menstruation by fourteen and by four exposures. In the first case the menopause was complete; in the other there was merely arrest of menstruation, but this put an end to the monthly periods of fever and the recurring congestion, and this patient soon considered herself completely cured. The condition of the lungs in the other case also has materially improved.

*Chest-Head Percussion Sign. P. Busacchi.—p. 385.

*Resection of Intestine for Obstetric Injury. E. Cartolari.—p. 386.

Chest-Head Percussion Sign.—Busacchi applies his left hand flat to the parietal region of the subject seated with trunk bare and head bent forward. He then taps lightly with the percussion hammer on the posterior wall of the thorax. The shock from the light blow of the hammer is felt by the palm held against the head. He calls this the thoracocephalic phenomenon, and describes the characteristic modifications in it with pleurisy or pneumonia, or other conditions impeding transmission of the vibrations.

Obstetric Injury During Embryotomy.—After embryotomy on a dead seven-months fetus, a loop of intestine appeared at the vulva, perforated at several points. It sagged through the lacerated posterior fornix, and the uterus was likewise torn. A laparotomy showed that a long stretch of bowel had been torn from its mesentery, and Cartolari resected 2.3 meters of the small intestine, joining the ileum to the cecum after vaginal hysterectomy. Recovery was prompt and uneventful.

*Diphtheria of Nose and Ear in Infant. L. Spolverini.—p. 785.

*Congenital Cysts in Neck. C. Romano.—p. 790.

Results of Artificial Feeding at Well Baby Clinic. A. Borrino.—p. 805.

Diphtheria of Nose and Throat in Young Infant.—The infant was only 30 days old, and the coryza and otitis seemed amply explained by the syphilis of the parents. The mother's statement that the discharge from the nose had been mixed with blood and had kept up for ten days, worse at night, led to bacteriologic examination. This revealed diphtheria bacilli in both the nose and ear secretions. No case of diphtheria was known in the environment. Spolverini comments that this case suggests that chronic otitis media in young infants may be the work of diphtheria bacilli more often than hitherto suspected. There was nothing about the otitis in this case to suggest the diphtheric origin.

Congenital Cysts of the Neck.—Romano gives the details of six cases in which he operated. Three of the patients were young adults, the dermoid cyst first becoming manifest at 8, 10 and 25, and gradually increasing in size. In the three children the cysts were serous and multilocular, and they had increased in size slowly from a small bunch noted early in two of the cases. The cysts in the third child formed a mass on one side of the neck as large as the head. The infant was only 10 days old when Romano aspirated the contents of each of the six cysts forming the mass. The fluid returned, requiring repeated aspiration, and finally some of the cysts suppurated. Aspiration of the contents and irrigation with a weak solution of tincture of iodine finally completed the cure, and by the time the child was 4 months old the neck was symmetrical in aspect except for the series of small scars. In the boy of 12 the multilocular cyst was not very large and it was easily enucleated, but in the child of 2 the cyst mass was larger than its head, and was suppurating when first seen. Adhesions hampered the operation, and success was realized only after repeated evacuation, drainage and disinfection of the cavity and fistula. If the cysts do not interfere with breathing and eating, he advises to postpone the intervention until the child is a few years old.

*Hyperexcitability of Muscles in Tuberculosis. P. Verrienti.—p. 571.

Present Status of Typhus Fever. A. Lustig.—p. 573.

*The Negri and Lentz Bodies in Rabies. R. Giurato.—p. 577.

Hydatid Cyst of the Spleen.—In the case described, a dull ache and occasional violent pains in the left flank were explained by an elastic tumor beneath the costal arch. Cardarelli put one hand on the back, the other hand on the front, over the tumor, and pushed suddenly, from one hand to the other and back again. He has always noticed that

when the tumor seems to show the movement from the front hand more, then the tumor is in or near the spleen, while it is in or near the kidney if the movement is transmitted better from the rear. This sign pointed to the spleen in this case, and the good general condition during the eighteen months, the absence of fever, of urinary and all other functional disturbances, and the fact that the descending colon lay to one side of the tumor, confirmed this assumption, and suggested a hydatid cyst. He has witnessed four cases of severe by-effects from exploratory puncture with a Pravaz needle, one proving fatal, consequently he punctured with an aspirating apparatus, without wasting time on medical measures. The fluid showed an active cyst, but there was 1 gm. and more of albumin in the 800 c.c. of fluid. He accepts this as a sign that the cyst is dying, and will continue this aspirating treatment, ready to operate at need. In another case, aspiration once a month for a year cured completely, and the cyst has never returned. But as a rule he advises surgical intervention if the cyst returns.

Diffuse Phlegmonous Gastritis.—The man of 39 died the seventh day from the first sudden onset of stomach symptoms, violent pain and vomiting, soon accompanied by fever and chills. The vomiting stopped the fourth day, and diarrhea developed. Pus and epithelial cells were found in the vomit; the stomach region was tender, and the man lay in bed bent over forward. Necropsy confirmed the diffuse phlegmonous gastritis with streptococci. Surgical intervention should be considered in the circumscribed form, and Mikulicz reported a cure in one diffuse case.

Muscle Signs in Tuberculosis.—Verrienti describes the hyperexcitability of the muscles impregnated with the tuberculous toxins. It can be rendered manifest even early in the disease by light finger-finger percussion of a muscle or tendon, which can then be felt contracting under the fingers. Sometimes a group of muscles contract and lift the scapula, or twist the arm, etc. The rise in temperature after physical exertion is probably from absorption of the toxins liberated by the muscles during the exercise. The heart muscle and the fibers in the vessels feel the toxic effect like other muscles.

The Negri and the Lentz Bodies in Rabies.—Giurato states that recent research has confirmed anew that these bodies are not parasites but only products of cell reaction.

Echinococcus Disease in Cattle.—Llambías describes with illustrations a multilobular echinococcosis he has been studying in some cattle in Argentina.

Bone Implants in Tuberculous Joints.—See abstract below.

Early Excision of Gastric and Duodenal Ulcers.—García has had 59 operative cases under long surveillance out of the 683 cases of gastric ulcer he has treated in the last ten years. He has gradually become convinced that early operative intervention is the only treatment for cases in which there have been two or three attacks. If the crises are very severe or occur often, it should not be delayed. In old cases, gastro-enterostomy is all that can be done, but the surgery of tomorrow, he reiterates, will be early excision of the ulcer. His 59 patients had been suffering for many years, and there were complications in 5 (fatal in 4), but all the others were cured by the gastro-enterostomy except 2 with fatal pneumonia or embolism, one with peptic ulcer, and one with cancer later. In 26 of the 59 cases the ulcer was in the duodenum.

Adenoids and Tonsils.—Martino states that tonsillectomy in the period 1900 to 1910 was very seldom followed by grave operative complications, but since then the literature shows that the number of cases of severe postoperative hemor-

rhage and death has been very large, both in adults and in children, as the operations have become more radical. He contends that for physiologic reasons, as well as on account of the operative dangers, tonsillectomy should not be done on children; the infected crypts should be emptied and disinfected. He insists that the actual cautery should never be used, as this obliterates the outlet to the crypts.

Bone Implants in Treatment of Active Tuberculous Process.

—Robertson declares that the method he describes opens a field for conservative surgery to aid the natural processes

BONE IMPLANT
TUBERCULOUS TISSUE
SOUND TISSUE

Bone implants with tuberculous arthritis.

of repair. He does not excise the tuberculous tissue in the knee, for example, but inserts two strips of bone from the tibia, implanted in sound tissue on each side of the joint. The ends of the bone strips are buried in the sound bone above and below the diseased joint, which they bridge on each side. Sometimes he drives pegs slanting through the sound bone into the epiphysis, traversing the cartilage but stopping short of the tuberculous lesion. He keeps up extension in a cast for three months and begins with extension and traction for two weeks before supplying the implants, to render conditions more favorable for them. They induce a reaction osteitis which starts processes of repair, and they supply material for the repair. The implants should be chiseled out, never sawed, as the bone sawdust clogs the openings in the bone and prevents the growing in of new vessels. No foreign body, thread or wire, should touch the implants. The ends of the latter should fit into the subcortical tissue, beneath the periosteum, but not extending to the marrow cavity. The osteitis induced by the end of the implant in the epiphysis may block the circulation to the tuberculous tissue and compel its atrophy. The pegs traversing the cartilage serve to drain away venous blood. The side implants in his cases grew in six months from the size of a toothpick to that of a rib. The patient can get up after three months, a light plaster cast still immobilizing the joint. When roentgenograms and palpation fail to reveal anything left of the lesion, he removes the subcutaneous side implants, and in ten or twelve days afterward begins massage. The osteitis serves as revulsion and the general health shows promptly the benefit from this.

Serologic Reaction with Suppuration.—Ymaz has been working for ten years to produce a stable suspension of leukocytes which could serve for the serologic diagnosis of hidden suppuration. He reviews the research by others in this line, and describes a simple technic with which he obtains aseptic pus (from a turpentine abscess) in an

isotonic vehicle, and the whole keeps perfectly for an indefinite time. The precipitation reaction and the zone of contact reaction with this reagent were relatively negative in thirty-eight healthy controls and relatively positive in the five cases of suppuration tested.

Radioscopy of the Stomach.—Merlo gives thirty-two radiograms of the stomach and discusses the interpretation of the findings, especially the differentiation of organic and spasmodic stenosis.

Sign of Neoplasm Inside the Thorax.—Novaro recalls that Pitres demonstrated the displacement of the sternum toward the side containing a pleural effusion. The lung on the other side has to work extra hard, and this extra expansion forces the xiphoid appendix toward the other side. Novaro calls attention to the inverted displacement when there is a tumor in pleura, lung or mediastinum. The infiltration around the tumor and the tumor itself force the xiphoid appendix over toward the sound side. He gives the roentgen and necropsy findings in three cases which establish the reliability of this sign which, he says, might be called the inverted Pitres.

Suction Drainage.—Galindez describes the technic with which he has successfully drained by aspiration in cases of cysts in the lungs, bronchial fistulas and purulent pleurisy.

Hemoglobin Crystals.—Lacoste takes the blood clot with a small quantity of blood serum and carbon bisulphid, or ether, in excess, triturating in a mortar. A thick drop of the filtrate (through paper) is kept in the moist chamber until crystals form. He gives thirteen photomicrographs showing the characteristic crystals with different species of animals.

The Enzyme Reactions in Immunization.—Damianovich states that the oxydases in the blood were in larger proportions in patients with infectious diseases than in others, among 100 persons tested. In rabbits, the enzymes which cause oxidation processes increased in notable proportions when the animals had been inoculated with diphtheria or other infection.

Hydatid Cysts in the Liver.—Petty usually reaches the cyst through the pleura after resection of the ninth or tenth rib, suturing the diaphragmatic to the pleural pleura, leaving the diaphragm exposed. He describes his technic in detail. Forty-eight hours after evacuation of the cyst he applies the Dakin-Carrel treatment, and begins heliotherapy in a week. In his six cases of the kind, the cure was complete in thirty-six days on an average with this treatment; without the Carrel-Dakin procedure the average was fifty-nine days.

July, 1919, 9, No. 7

*Impending Eclampsia. R. Pacheco.—p. 541.
Sewerage System of Rio. Belmiro Valverde.—p. 567.

Eclampsia.—Pacheco applies this term to the condition just preceding eclampsia, and tells how to detect it in time and thus avert disaster. He declares that it is not enough to examine the urine for albumin. The specific gravity and the chlorid content in the twenty-four hours urine are the true index of the condition. The blood pressure should be taken whenever the pulse is hard and the output of urine reduced. The pulse curve is typical in this stage of hypertension, the prelude to eclampsia. This characteristic sphygmographic record differs in three features from the normal tracing: in the slope of the ascending line; in the plateau instead of the usual peak between the ascending and descending line, and in the almost total absence of the elevations of secondary waves. Pacheco gives the findings in over fifty pregnant women, all free from albuminuria, but with urine of a specific gravity of 1.010 or below. The arterial pressure was constantly high in all these cases and the pulse was of the characteristic type, confirming the imminence of eclampsia. Only this group of fifty were found among 300 pregnant women examined in the course of almost a year's research. The women found to be threatened

with eclampsia were kept on milk alone; in the extreme cases only water was allowed. Injections of sugar solution were useful to reduce the concentration of the blood and promote diuresis. Venesection two or three times a month, withdrawing not more than 100 or 120 gm. of blood at a time, helped to reduce the blood pressure and get rid of toxins. Purges and enemas aided in improving the general condition. A tendency to jaundice usually accompanied this precursor stage, and it promptly subsided under small fractionated doses of calomel, cascara, etc. Diuretics should be accompanied by total or partial restriction of salt, and no meat at all should be allowed. This article was awarded the Durocher prize by the Academia Nacional de Medicina. Pacheco's attention was called to eclampsia by the case of a young pregnant woman whose urine was free from albumin on repeated examination. Slight edema and slight headache one day led to investigation of the urine for the specific gravity, which was found 1.006, and large amounts of albumin suddenly appeared in the scanty urine. Convulsions followed the same day, and proved fatal in seven hours.

*Mentally Abnormal Children. E. Fernández Sanz.—p. 214.
*Fracture of Femur. F. Criado Aguilar.—p. 221.

Scabies and Osteomyelitis.—Martí reports a case of osteomyelitis in a child who had been having scabies for three months. The case teaches anew that a mild pathologic condition, like scabies, may open the portal to fatal infection. The extensive osteomyelitis required radical and persevering operative measures.

Mentally Abnormal Children.—Fernández describes the various measures required for three great groups of mentally abnormal children, the mentally backward, the mentally backward with some active psychopathy, and the abnormal children not mentally backward.

Fracture of the Femur.—Criado denounces extension as unreliable even for adults and much more so for restless children. His method of applying a cast to insure that the leg is exactly the length of the sound mate has already been described in these columns, when published elsewhere (Oct. 11, 1919, p. 1168).

Emulsion of Cod Liver Oil in Malt Extract. L. Morquio.—p. 446.

Gallop Sound in Children.—The gallop sound in the precordial region in the two cases described cleared up the diagnosis by suggesting acute nephritis. The child of 4 had no other symptoms except slight pathologic findings in the urine, and all promptly returned to normal. The child of 14 presented symptoms of endocrine insufficiency when the discovery of the gallop sound called attention to the kidneys. The acute nephritis in this case proved rapidly fatal. The circumstances in these and in other cases cited suggest that toxic action on the myocardium is responsible for the gallop sound in these cases, by weakening the heart action and thus entailing compensating dilatation.

Polyneuritis of Diphtheric Origin without Apparent Diphtheria.—Ponce de Leon reports another example of generalized polyneuritis, without pain or sensory disturbances, entailing merely general paresis in the child of 8. No cause for the polyneuritis could be discovered but certain features of it suggested diphtheric paralysis, and although the throat was apparently normal, diphtheria bacilli were cultivated

from it and under antitoxin rapid recovery ensued. The case teaches the wisdom of antitoxin treatment in dubious cases of the kind.

Primary Cancers of Lymph Glands.—Aberastury's patient was a healthy farmer of 70 who suddenly developed a chill and pains in the chest. In a month he noted a tumor near the umbilicus and another later in the right supraclavicular fossa. These tumors were hard and knobby. A number of lumps developed at other points, all hard, round and indolent, and the asthenia was extreme, although the man seemed well nourished, and there was no fever. By exclusion, the glandular lesions were assumed to be metastases from some hidden cancer, but the nine photomicrographs given show that the multiple lesions were all primary endotheliomas of the lymph glands. Aberastury knows of only seven cases on record approximating this.

Arrhythmias. P. M. Barlaro.—p. 196. Cont'n

Chronic Parametritis.—The two cases described by Castaño were of the type with atrophy to which Freund first called attention. The persisting pain is evidently the result of compression of nerves from the sclerosis in the connective tissue. There is a history of untreated syphilis in both his cases, and in addition to specific treatment, he has ordered massage to promote the circulation and ward off atrophy of the internal genitals, and gymnastic exercises of the bicycle type. He is also applying hot air, and is considering diathermy and ovarian treatment. Pulvermacher has recently reported benefit from rectal injection of iodized paraffin, the latter acting on adhesions. He mixes 5 gm. of paraffin at 75 C. with 90 gm. of liquid paraffin. When cooled to 45 C., he adds 10 or 15 drops of tincture of iodine. The syringe is heated in boiling water and the mixture is injected about 6 cm. above the anus.

Diagnosis of Pleural Effusion in Young Children.—Martínez found normal resonance in the chest of the child of 2½ with ordinary percussion, but when the percussion was extremely gentle, the child sitting up without support, except for its hands, dullness was found in the entire left side of the chest, and puncture in the ninth interspace released an effusion. The coexistence of a vesicular murmur was misleading at first.

Revista Española de Medicina y Cirugía, Barcelona

- *Double Operation for Gangrenous Hernia. G. Estapé.—p. 595.
*Symptom of Hyperthyroidism. G. Marañón.—p. 598.
*Radiocardiometer. B. Navarro Cánovas.—p. 600.
Pathology of the Skin in Relation to Pathologic Brain Conditions. E. de Oyarzabal.—p. 604.
Electrocardiography in Pathologic Conditions. R. Dargallo.—p. 607.

Treatment of Gangrenous Hernia.—Estapé opens up the hernia as usual, but if he finds evidence of gangrene he packs gauze around it and makes a vertical incision some distance above, at the margin of the anterior rectus, and hunts for the afferent and efferent portions of the loop forming the hernia. He then makes an anastomosis between them, with a button, and sutures the incision. He then returns to the gangrenous herniated portion of the loop and fastens it to the skin, amply protected with gauze. When this bowel sloughs open he treats it until the loop is harmless and the fistula heals, which takes about twenty-eight or thirty days. This procedure applied in two cases gave excellent results. The course of the feces was reestablished from the start, while, after draining, the gangrenous loop healed naturally. He warns that fresh gloves should be taken at each step of the operation, and emphasizes the necessity for operating a strangulated hernia within twenty-four hours to ward off gangrene. Two illustrations show the technic with inguinal hernia.

Vasomotor Symptom of Hyperthyroidism.—Marañón found in ninety-two of 100 cases of hyperthyroidism that rubbing the skin in the neck lightly with the fingers made it turn very red in the region of the thyroid, a much brighter red than could be elicited by rubbing the skin in the same way elsewhere. This vasomotor reaction may be more pronounced in the milder cases, and is more distinct in the nervous, in women, in the young, at the menopause, and in persons inclined to sympatheticotony rather than vagotony. He has not seen any mention in the literature of this induced localized erythema in the thyroid region; it may be a uniform or irregular redness, and there may be slight swelling of the red patches.

Radiocardiometer.—Remigio Dargallo comments on the lack of accuracy in estimating the size of the heart unless the very complicated orthodiagraphy method is used. He has found that the ratio between the diameter of the heart and the widest diameter of the chest is almost constant in health. The normal heart forms 42 per cent. of the chest diameter; 33 per cent. of the remaining diameter lies to the right and 25 to the left. When the subject reclines, the heart spreads out a little, so these figures are modified to 44, 35 and 21. He gives an illustration of a chart scale marked off in hundred squares, in perspective, the different rows of squares corresponding to different sized chests, with the squares corresponding to the normal heart area marked. This radiocardiometer is made of transparent celluloid, and by laying the scale on the chest or on the screen, with the row of squares just corresponding to the diameter of the individual chest, it is easy to see any encroachment of the heart shadow beyond the area it should normally occupy.

Intermittent Ileus in the Pregnant.—Villanueva states that autointoxication was pronounced in the two pregnant women with intermittent ileus he has recently encountered, and he ascribes it to spasmodic contraction from toxic action. In both, uncontrollable fecaloid vomiting preceded and accompanied the intermittent occlusion of the bowel, and one of the women died the fifth day after induced premature delivery. The other woman was treated at the fifth month with measures to arrest the tendency to spasm of the bowel and cure the autointoxication, and she was thus tided along until term, and parturition was physiologic. The main reliance was on two or four injections of morphin, with atropin, hot enemas, with a little milk by the mouth and scraps of ice.

Nervous and Mental Disturbance After Ovariectomy.—Mendoza summarizes nine cases in which the artificial menopause induced unusually severe nervous disturbances and change in character. No benefit was realized from organotherapy in most of the women. In the most refractory cases an element of hysteria or neurasthenia was manifest. One woman of 40 had attacks of unconsciousness, besides the usual phenomena of the menopause; no benefit was obtained from ovarian treatment but under ergot for a time conditions gradually returned to normal. Headache, insomnia, neuralgias and pain in the lumbar region were common.

Psychopathography.—This is a short story written by a young man with paralytic dementia. It is reproduced as a specimen of psychopathography.

Splenectomy in Banti's Disease.—In Ceballos' three cases the disease was in the third or ascitic stage; the patients were three men between 22 and 28. The easiest mode of access was with the patient lying on his right side, his back at an angle of 45 degrees with the surface of the table. The left arm, in extreme abduction, is raised toward the head, which raises the base of the thorax and the stretched muscles. The surgeon stands at the patient's right. With his right hand he can pivot out the spleen; as it lies on the abdominal wall, the vessels in the pedicle can be easily seized and adhesions to the diaphragm broken up more readily than from the left side. If the spleen is excessively large, it might be wiser to ligate the artery in the pedicle and wait for the organ to atrophy rather than remove it at once.

Benzol in Leukemia.—Pignetto reports two cases of myelogenous leukemia in which marked improvement followed benzol treatment. The first patient was a woman of 45; the erythrocytes increased from 2,000,000 to 5,000,000 by the eighty-third day, the hemoglobin from 60 to 88 per cent., while the leukocytes dropped from 600,000 to 7,500. She took 2 gm. benzol daily at first and increased to 5 gm. without any signs of intolerance except at first and toward the last, compelling brief suspension of the treatment. A total of 256 gm. was thus taken. She kept well for three months after the close of the course of treatment, and then returned to her home in the country and further details are not known. The second patient was a woman of 55, and the leukemia subsided somewhat under roentgen exposures three times a week for a month, the leukocytes dropping from 200,000 to 120,000. Then increasing weakness and other symptoms compelled abandonment of the exposures, and benzol was given, a total of 150 gm., with improvement as in the other case. It has persisted during the two years to date, with nothing left of the leukemia except the anemic complexion. This patient takes arsenic for twenty days each month.

Acute Colitis in Children.—Bravo found in his 50 cases last summer in children from 1 to 5 years old, that the streptococcus was mainly responsible, alone or associated with the colon bacillus. The colitis accompanied or followed streptococcus lesions elsewhere, or became associated with a streptococcus lesion of the skin. Pyelonephritis frequently followed the colitis, which emphasizes the share of the colon bacillus in the process. In 35 per cent. of the 50 children, a febrile bronchitis just preceded the colitis, but 2 children developed it at the same time as other members of the family were having influenza. Only 2 of the total 50 were breast-fed; the majority were eating at the family table, and the premature use of meat, eggs and cheese may have afforded a predisposition.

Serodiagnosis of Syphilis.—Morató states that the Sachs-Georgi test gave findings that paralleled the Wassermann test more closely than any other of the various serologic tests applied.

Bacteriologic Prognosis of Typhoid.—Ruiz de Arcaute refers to some recently published cases in which the total absence of agglutination and of bacteria in the blood coincided with a promptly fatal course. He warns that even the most apparently typical necropsy findings do not justify the absolute diagnosis of typhoid unless the stools have been examined.

Tuberculosis of the Mesenteric Glands.—Primary tuberculosis of the mesenteric glands, Gehrels finds, is not so well known as the secondary form, in spite of its greater importance. The diagnosis of the primary form is important because it is so often confused with surgical diseases, especially appendicitis. The disease is produced by tubercle bacilli entering from the intestine. The bovine type of bacillus is common. The favorite site of the disease is the lymph glands of the ileocecal region. Children are more frequently affected than adults, which is owing to the greater permeability of the intestinal mucosa. Abdominal pains, usually localized in the ileocecal region, are the most important initial symptom. Acute symptoms often resemble those of tuberculosis of the peritoneum. Fever is usually present at the onset. Insatiable hunger (bulimia) and denutrition, accompanied by secondary anemia, are characteristic symptoms. The intestinal disturbances vary and are not typical. Blood in the stool points rather to tuberculosis of the intestine. He adds that two roentgenograms of the abdomen should be taken several days apart for purposes of comparison. The most important clinical complication is ileus. The lack of abdominal distention and the abdominal sensitivity to pressure help to differentiate the disease from appendicitis, which it resembles in its earlier manifestations. Tuberculosis of the mesenteric glands is more amenable to treatment than any other form of tuberculosis: forced feed-

ing, change of climate, artificial heliotherapy, deep abdominal roentgenotherapy, and tuberculin injections. Surgical intervention is indicated only when long continued internal treatment has failed. Mesenteric abscesses may demand an operation. Various types of operation are to be considered: radical extirpation of the diseased glands, excochleation, abscess puncture, and explorative laparotomy in diffuse conditions in which assailable glands are not readily recognized.

The Therapy of Pernicious Anemia of Unknown Origin.—

That it is a long and weary road that both physician and patient have to travel before cryptogenetic pernicious anemia can be cured, Zadek readily admits; in fact, an absolute cure is exceedingly rare. He has, however, by his mode of treatment been able to effect marked improvement in seventeen cases. He orders rest in bed until remission occurs, which usually requires from four to six weeks. The patient may then be allowed to sit up for longer periods each day. The diet should consist mainly of milk, vegetables, cereals and fruit; twice a week, boiled meat (no sausage or smoked meat); cheese and eggs in small quantities; reduced liquid intake (no soup). As medication he advises: three times daily by mouth, 20 drops of hydrochloric acid; after an early supper, 20 gm. of animal charcoal in wafer form; every second day subcutaneous injections of a thoroughly neutralized 1:100 solution of sodium arsenate, beginning with one scale unit of the Pravaz syringe and increasing one unit at a time up to 1 c.c.; in exceptionally severe cases up to 2 c.c. For one or two weeks injections of the same quantity are given; then they are decreased down to 0.1 c.c. again. Weekly intravenous injections of neo-arsphenamin in increasing doses: 0.15, 0.3 up to 0.45 gm., for from four to six weeks are given. Daily, alternating gastric and intestinal lavage is done. For the gastric lavage, which is given mornings before breakfast, from 12 to 15 liters of lukewarm water are used, to which 3 gm. of sodium salicylate or phenyl salicylate have been added. The intestinal lavage is usually given evenings (in the genucubital position) with a chamomile decoction, or, if there is a tendency to constipation, a soapsuds enema is used. The lavages are usually kept up until the arsenic treatment is discontinued, but often for weeks, and occasionally for years. Zadek states that the outlined treatment is certain, in a few weeks, to bring about an extended remission.

- *Retrograde Herniotomy. Kinscherf.—p. 276.
- *Foreign Bodies Impacted in Esophagus. L. Zindel.—p. 281

Indirect Inguinal Hernia.—Ledderhose devotes over fifty pages to this study of the structure of external and encysted inguinal hernia, its mode of development, especially the congenital type, the recurrences after herniotomy, the relations with the omentum, various anomalies such as a lipoma in the inguinal canal, and the features, the microscopic in particular, which differentiate the direct and the indirect types. The minute findings in twenty operative cases are recorded.

Operations to Restore Eyelashes.—Esser gives an illustrated description of the method he has applied in a number of cases to restore missing lashes, by taking a strip from the eyebrow to suture to the edge of the lid. He first splits both eyebrow and eyelid lengthwise, and sutures the near lips of each together, forming thus a kind of tunnel lined with skin. When this has healed, he sutures the other lips together, the upper part of the eyebrow and the lower part of the eyelid, covering up the other suture. Then an incision is made through both, just below the hairs in the eyebrow and just above the hair strip that was first sutured to the upper lip of the lid. This leaves the eyelid with a strip of hairs. The various steps of the operation in two cases are illustrated; they are not cited as very successful cases.

Operative Treatment of Cardiospasm.—Pamperl reports two cases of inveterate cardiospasm in which he opened the stomach and stretched the cardia for half an hour until he could work four or five fingers of one hand through it. Notwithstanding this unprecedented stretching of the cardia and the excellent immediate results after the operation, the cardiospasm now displays a tendency to return. The contrast meal four months later showed a distinct retarding of the passage through the cardia, even when there was no disturbance in swallowing. By the tenth month this was more pronounced, and the patient feels that the food tarries above the stomach when she is excited. The other patient seems to be subjectively cured although the bismuth suspension does not pass entirely at once into the stomach. Even with this possibility of return of the cardiospasm, he regards this stretching method, without cutting the cardia, as the preferable technic when systematic efforts at dilatation with sounds from the mouth have failed to relieve. He tabulates the fine results realized with this dilatation from below in sixteen cases on record, comparing with it eight cases in which various surgeons applied other operative measures.

Spontaneous Dilatation of the Carotid Artery.—Deus describes three cases of bulging of the carotid simulating an aneurysm and requiring operative intervention. He compares with these the few cases on record of suture of the carotid artery for aneurysm. There was only one fatality in the list.

Forward Dislocation of the Atlas.—Naegeli reports the tardy paralysis and final recovery in a case of forward luxation of the atlas from a fall on the head from a load of hay. The case affirms anew the importance of prolonged repose in such cases, with the spine and neck immobilized in plaster. Only solid growing together of the parts ensures a permanent cure and wards off tardy complications.

Retrograde Herniotomy.—Kinscherf applies this term to an operation through the inguinal canal to reach the obturator hernia in sound tissue, above the incarcerated portion of the loop.

Impacted Foreign Bodies in the Esophagus.—Zindel has encountered thirteen cases of this kind in the last thirteen years. The esophagus was incised in five cases as the coin or set of false teeth could not be released. In two cases there was hemorrhage the fourth or fifth day after the operation, fatal in one child. The attempt to push the soft or smooth foreign body down into the stomach failed in only one case; in this, a cherry stone had caught at a stricture left from an old caustic erosion.

Cancer-Destroying Organic Acids.—Previous research by Freund and Kaminer had shown that normal blood serum and normal tissues contain an organic fatty acid having power to destroy carcinoma cells. They have not succeeded as yet in establishing the exact formula of this fatty acid, so they refer to it as the "normal" acid, since it is the protective substance of normal cells. Carcinoma serum and carcinoma tissue, they find, do not contain this "normal" acid, but they do contain an unsaturated fatty acid that counteracts the effects of the "normal" acid, and thus forms a protective substance for the carcinoma cells. This acid they term the "carcinoma" acid. They have therefore come to regard the conflict between the human organism and the invading neoplasm as a conflict between two opposing substances. They admit that questions pertaining to the nature and origin of the "carcinoma" acid may be more important, but from the therapeutic aspect the analysis and production of the carcinolytic "normal" acid is also important, for they believe that if the "normal" acid can be produced in sufficient quantities, the growth of carcinoma cells can be at

least checked. Comparing the neutralizing properties of the two acids, they find that at least ten times as much "normal" acid as "carcinoma" acid is required to neutralize a given alkali. This, they think, explains the fact that concentrated solutions of "normal" acid, derived from horse serum, while they had some effect on epitheliomas; proved in the end no match for the much stronger "carcinoma" acid. Concentrated solutions of the "normal" acid being difficult to produce other than in small quantities, they conceived the idea of replacing it by a synthetic product. Starting with an analysis of the "normal" acid, they claim to have discovered the series of acids to which the "normal" acid belongs; namely, the saturated dicarboxylic acids. They have tested the action of various members of this series on carcinoma cells, and find that, while certain members exert a cytolytic action on these cells, others do not; for example, oxalic acid and malonic acid were not effective, whereas succinic acid was effective. Again, adipic acid and pimelic acid were not effective, whereas suberic acid was effective. This finding in itself is significant, that within a series of acids some members are cytolytic and some are not. Acids of many other series were tried; none of them proved to exert a cytolytic effect on carcinoma cells. Freund and Kaminer admit that they are still far from synthetic production of the required substance, but think that having found the series of acids to which it doubtless belongs, the way for further progress is clearly mapped out.

*Zinc Chlorid in Treatment of Uterine Hemorrhages. H. Hellendall.—p. 969.
*Reinfusion of Blood Lost from Tubal Abortion. E. v. Arnim.—p. 971.

Zinc Chlorid in Treatment of Uterine Hemorrhage.—Hellendall reports a case which warns against this method of treating uterine hemorrhage as it entailed complete occlusion of the cervix. Hematometra followed, with paroxysms of pain compelling supravaginal amputation of the uterus.

Reinfusion of Blood from Tubal Abortion.—Von Arnim relates that in twelve of a recent series of 135 operative cases of extra-uterine pregnancy, she reinfused into a vein from 300 to 1,000 c.c. of the woman's own blood, diluted with an equal amount of physiologic sodium chlorid solution with a little sodium citrate. The blood was scooped or soaked up from the abdominal cavity and passed through a funnel over some gauze as a filter. From the filter the blood passed into a receptacle containing the salt solution. The women recuperated from their moribund condition surprisingly fast. By the next day the pulse was good and full, the lips red, and strength was rapidly regained. The reinfusion caused intense cyanosis in one of the women, and attacks of pain in the chest with dyspnea and a chill in two others. Toxic action from the dying blood might explain these by-effects. Nothing suggesting edema in the lungs was evident in the one fatal case, the woman succumbing to peritonitis. This was the only fatality in these twelve reinfusion cases. The reinfusion consequently should be attempted only when the hemorrhage is recent. No case is known of embolism from reinfusion. No woman should be allowed to bleed to death after an operation for extra-uterine pregnancy, she affirms in conclusion, without having reinfusion attempted at least.

*Recent Works on Pharmacology. C. Bachem.—p. 929.

Recent Works on Pharmacology.—Bachem reviews recent German literature on the action of drugs, old and new. One writer extols strychnin for its prompt efficacy in circulatory disturbances from paralysis of vessels, as in shock, collapse from poison, etc. The daily subcutaneous or intravenous dose of 3 or 4 mg. acts rapidly and does no harm. Silver salvarsan is extolled by some as the most potent treatment for syphilis yet known, but angioneurotic by-effects seem to occur more frequently than with other salvarsan preparations, according to some. Hoffmann has compiled cases of drug eruption transmitted by the mother's milk, bromid, salvarsan and acetylsalicylic acid eruptions. Instances of this are not so common as generally assumed. Several cases of poisoning from hydrocyanic acid are mentioned; it was inhaled in exterminating vermin. Fühner advocates as an antidote subcutaneous injection of a 5 per cent. solution of sodium thiosulphate (hyposulphite). Another writer warns that injections of caffein seemed to favor gas gangrene.

Mededeelingen v. d. Burg. Geneesk. Dienst, Java

Report on Dysentery Epidemic. E. P. Snijders and R. Pratomo.—p. 1.
*Breeding Places of Mosquitoes. N. H. Swellengrebel and J. M. H. Swellengrebel-de Graaf.—p. 39

Breeding Places of Mosquitoes.—Swellengrebel and de Graaf here report further research on the requirements of different species of mosquitoes for their breeding places. The different species seem to be constant in their habits but these habits differ in different species. They assert that their comprehensive and minute research in Java has apparently established that it is hopeless to attempt to do away with the breeding places for the larvae of the dangerous anophelines of the ubiquitous hill or shade-preferring kinds. They are not particular as to their breeding places, and general sanitation seems at present the only means of combating their larvae. The ludlowi, however, is so exceptionally dangerous, that special measures against it might be considered, including the doing away with its salt-water breeding places. This does not offer much hope of success, however, in view of the fact that if the more favorable breeding places are destroyed, the ludlowi might be driven to utilize other breeding places.

Hygiea, Stockholm

Formation of Corpora Lutea in the Ovaries. A. Westman.—p. 865.
*Treatment of Leg Ulcer. H. I. Schlasberg.—p. 880

Leg Ulcer.—Schlasberg emphasizes the importance of excluding syphilis and tuberculosis before treating a varicose ulceration. One woman with a positive Wassermann reaction had been treated for two years on the assumption that the ulcer was a syphilitic lesion. When this assumption was disregarded and treatment applied as for any varicose ulcer, the lesion soon healed. His method is to soften and cleanse with Burow's solution for three or four days. Then he applies a plaster, 24 gm. solution of lead subacetate and 136 gm. lead plaster mixed and spread on a 2,000 sq. cm. cloth. This plaster should extend 2 cm. beyond the edge of the ulcer. The leg is then wound with a bandage from ankle to knee. The bandage is taken off every day, and if there is much secretion the plaster is renewed; otherwise the plaster may be left, but not for longer than three days. In two weeks healing is evident and is soon complete, while there has been no interference with the earning capacity, and no impairing of the circulation as when the elderly have to stay in bed. This method has been applied to 21 men and 29 women in the last seven years. The ulcer was over three years' standing in 20 cases, and one to three years in 19. The area covered by the ulceration ranged from 3 by 2 to 15 by 13 cm. The lesion took from sixteen to 197 days for the complete cure. Recurrence is known in 6 cases, in from three to twelve months, but these patients had not followed the advice to wear the bandage for a time after the ulcer had healed.

TUBERCULOSIS AS A FOCAL DISEASE *

EDWARD JACKSON, M.D.
DENVER

It is sometimes important to get a new point of view for those serious problems that are most constantly with us. Like moving from one house to another, it brings to light things that have been forgotten, and loses others that were constantly in evidence. If we can do this with regard to tuberculosis, if we can bring out old facts that have been neglected and see them with a new significance, if we can lose some of our misconceptions that have been too constantly with us, hiding the real significance of what we observe, it may be a profitable use of our time.

GENERAL AND FOCAL DISEASES

A focal infection is an infection of some part of the body, localized by the defensive reactions of the tissues. Tuberculosis is the sum of the defensive local and general reactions of the organism against the tubercle bacillus, and the sequels of such reactions. We have commonly thought of tuberculosis as a chronic general disease.

In a sense we have no such thing as local disease in the human body. Injury to the smallest and most distant part produces general reactions of the whole organism, whether the injury be mechanical, chemical, or due to bacterial invasion or simply to strong emotion. That is what our connecting nervous and vascular mechanisms are for. Any imperfection or excess of such reactions, and also their most perfect adaptation to their purpose, constitute disease. They reach every part of the body. A professional colleague administered an ill-advised remedy to his daughter, resulting in her death. Three months later he pointed out on each of his finger-nails the transverse furrow which marked the influence of the nervous shock on every epithelial cell that had been in a certain stage of development.

What we call general diseases exhibit their characteristic changes only in certain portions of the body, as scarlet fever or measles in the skin and mucous surfaces, or typhoid in the intestinal lymph glands. Away from these regions of acute disturbance, physiologic function is carried on much as in health. Just as in France during the war, beyond the sound of the guns and out of the region of air attacks, the life of the community and the production of food continued along the same lines as it had in the years before the

German assault on civilization. At certain points war disorganized everything, destroyed everything, substituted its activity and accumulations for those of peace. The whole nation felt the effect of war; but its characteristic and obvious changes were localized. These were foci of war, and in quite a similar sense we speak of the foci of disease—of focal infections.

Every focus of infective disease is a point of attack and defense, of armed aggressive force. The opposing forces may be for the time accurately balanced, may sink into a state of siege, or only keep up the minor exchanges of trench warfare; but there is always present the aggressive disposition and the possibility of attack intended to annihilate all defense, and carry the warfare into new fields, there to produce a similar devastation. That is the nature and significance of every focal infection.

The typical tubercle is a typical focal infection. It is created by the reaction of the invaded tissue to the injurious influences of a colony of tubercle bacilli, sufficiently numerous and sufficiently virulent to establish themselves in that particular locality, and make their influence felt. It exhibits all grades of pathologic achievement, from massing of leukocytes and the proliferation of fixed tissue cells required to resist invasion, through degenerated epithelioid and giant cells to fatty, cheesy and calcareous masses of cell debris. It is a lesion preeminent in the length of the siege that the invading bacilli can withstand, maintaining their vitality to sally out when conditions become more favorable, and plant new colonies; thus to repeat the same process in other parts of the body. The single tubercle with these characteristics is the organic basis of tuberculosis; the essential feature of the disease, the one that all cases have in common, and the entity complete in itself. Tuberculous organs or regions are areas in which multiple foci have been massed.

The other phenomena that have been grouped in our minds to form the clinical picture of tuberculosis are occasional, incidental and temporary. They belong with coincident infections and complications, or are connected with a certain stage or particular locality of the focus of tuberculous invasion.

HISTORY OF TUBERCULOSIS

The history of our knowledge and recognition of tuberculosis is peculiar. Typhus and typhoid fevers, absolutely distinct diseases, were long confused. "Abdominal typhus," "typhus exanthématique" are terms that still remind us of the period when efforts were made to distinguish between them. Gonorrhea, syphilis and chancroid were all regarded as one disease. The terms "French measles" and "German measles" commemorate the classing with measles of a roseola or röteln. One dysentery was classed with

* President's address, read before the Medical Society of the City and County of Denver, Jan. 6, 1920.

another, as though they were the same disease, and not in some respects strongly opposed to one another. They still are called dysenteries in loose phraseology; much as the "gutta serena" of older writers embraced whole classes of affections of the deeper tunics of the eye.

But with tuberculosis quite the opposite was the case. Phthisis was one disease, scrofula another, Pott's disease and coxalgia were quite independent. Pulmonary hemorrhage, pleurisy, cold abscess, and lupus were not thought of as having any essential in common, or with meningitis, or chronic pyelitis, or recurring vitreous hemorrhage.

Only when the causative bacillus was recognized and studied, and established as pathogenic, did the finding of it with these different clinical manifestations connect them up into the general modern conception of tuberculosis. So much does locality modify these manifestations, that it never had occurred to the students of disease that they all were of one and the same origin.

When I studied medicine, scrofula was one of the most important, confused and obscure conditions described in the textbooks, and among the first to confront the young practitioner. It was suspected then, as was known a few years later, that it was nine-tenths tuberculous, and one-tenth other confusing chronic conditions. But it had come down to us from Hippocrates as a distinct pathologic diathesis, or constitutional disease resting on a diathetic tendency, for which there was as much prospect of discovering a specific cause as there was for syphilis or tuberculosis. The anatomic investigations of Virchow had only added to the confusion.

Hip joint disease, clinically recognized and studied for 2,000 years, had then been subjected to the microscopic investigation that identified the tubercle. In 1779 the famous surgeon, Percival Pott, had published "Remarks on That Kind of Palsy of the Lower Limbs Which Is Frequently Found to Accompany a Curvature of the Spine." This condition had been followed back toward its etiology far enough to recognize in it the ubiquitous tubercle. The tubercle itself had risen to due prominence in connection with pulmonary tuberculosis through the work of Bayle and Laënnec almost 100 years ago. And sixty-four years ago Villemin had shown that it was infectious.

Koch's discovery of the bacillus caused the rapid crystallization of our present views regarding tuberculosis; but the importance of the latent focus of infection, and its bearing on our theory of etiology and treatment are still not fully appreciated. Even the author of "Cellular Pathology" failed to recognize that what he called "caseous hepatization"—the tuberculous infiltration of Laënnec—was but the débris of the bacteriocellular tuberculosis battle.

THE TYPE LESION IN THE EYE

The single tubercle is the typical lesion of a focal infection; each is complete in itself. The crowding of many tubercles into one larger mass has always tended to obscure the real character of the disease, by raising issues and causing symptoms that were incidental and nonessential; it has tended to draw attention away from the smaller fields of the vital struggle in which the real battle of defense against the invader was being fought. But a single tubercle usually is not recognized in the living body. Generally a large number of single tubercles developed in the same region, as

in a lymph node or a lobule of the lung, have been spoken of as the focus of infection.

Much that applies to the single tubercle applies to the larger mass; but a better insight into the nature of the disease began with the anatomic study, the microscopic analysis of the single tubercle; and there are important lessons still to be learned by the study of the evolution of such a lesion, and the careful noting of the symptoms it causes during life. There is one place in the body where such a study is possible, the background of the eye; and when the ophthalmoscope has been properly and persistently employed in this investigation, we shall have learned some very important facts with regard to the pathology of tuberculosis. The tubercle present in the ocular fundus varies in dimensions, being 0.1 to 1 mm. or larger. It can be watched often from its beginning to its complete involution. It may be recommended as a subject for study to all who are interested in tuberculosis.

Choroidal tubercles, as a late symptom in tuberculous meningitis or general miliary tuberculosis, were recognized early in the use of the ophthalmoscope. The first report regarding them was made by Manz in 1858. But when they appear in these cases, the patient is nearing the fatal termination of his disease; and only their initial stage became familiar to ophthalmoscopists. If carefully looked for they may be found within a few days of the end, in 50 per cent. of these cases. About fifteen years ago, Stock, experimenting with rabbits, found that tubercles of the choroid, beginning with much the same picture already familiar in the human eye, ran a course that ended in patches of choroidal atrophy, similar to the patches of choroidal atrophy even more familiar in human eyes.

The same series of changes has now been followed out in human eyes, by numerous observers. The connection with tuberculosis in other parts of the body has been noted. The focal reaction of such lesions after subcutaneous injections of tuberculin has been watched. It is established that a certain proportion, and probably a large proportion of the patches of choroidal atrophy found in our routine ophthalmoscopic examinations, are patches of atrophy left by the healing of focal infections of tuberculosis. These atrophies show destruction of the normal tissue, pigment massing, ultimate thinning of scar tissue, sometimes hyaline change or even ossification; but no cheesy or calcareous débris.

More recently still we have come to identify tuberculous focal infections in the retina. For thirty odd years the clinical picture of recurring hemorrhage from the retinal vessels into the vitreous has been recognized as an important ocular condition, causing temporary and sometimes permanent blindness. Ligation of the common carotid has been done for it, sometimes apparently followed by the desired result, but more often by failure.

We know now that many of these hemorrhages, probably all in a distinct clinical group, are due to tuberculous focal infections in the retina. The hemorrhages in some cases are not massive, causing blindness and shutting off the view of the basic lesions with the ophthalmoscope, but are small enough to permit the watching of the causative lesion. In the Colorado Ophthalmological Society we have had the opportunity of watching several of these cases for periods running one, two or three years; and the observations are full

of interest, because of the light they throw on the focal infections of tuberculosis in general.

The retinal tubercle is generally clearly connected with a blood vessel: either an artery or a vein, but more frequently the latter. The vessels thus involved vary from 0.01 to 0.1 mm. in diameter. In the beginning the vessel appears normal, except that at the seat of the lesion it is covered by a yellowish white or grayish white, rounded cloud, with an indefinite margin. This area reaches its full size in a very few days. On either side of the tubercle the appearance of the vessel may remain about normal, or may change slowly. The arteries commonly show little alteration, except that the perivascular sheath may become visible as white lines parallel to the blood column. The veins are more likely to become dilated in limited portions, which may be several millimeters in length. Such a dilated portion may have three or four times the diameter of the normal vein at either end of it; and the dilated part may end quite abruptly. It is as though that part of the venous wall had been weakened by some noxious influence exerted on it, while other parts of the wall remained healthy.

After many days or several weeks, newly formed vessels are seen on the surface and periphery of the tubercle, attended with some increase in the size of the mass and more clouding of its edges (added exudates). The vascularity includes all sizes of vessels from swollen capillaries (which are easily distinguishable with the ophthalmoscope) to vessels almost as large as the trunk on which the tubercle is located. Then, very gradually the reddish gray area shrinks, becomes lighter in color, less vascular, and more transparent so that the fundus red shows through. Finally, the lesion fades away completely, leaving the vessels, the choroid and apparently the retina in the same condition as before the attack. This fact of complete resolution of some retinal foci of infection seems of great importance in its bearing on the possibility of complete healing of tuberculous lesions elsewhere in the body.

More frequently, the stage of peripheral vascularity and exudate does not go on to complete resolution. The gray mass becomes whiter but not transparent. It extends in certain directions, developing into a band or connecting bands of brilliant white fibrous tissue, on the surface of which stand out sharply a reduced number of blood vessels, often still quite tortuous. This condition, known as retinitis proliferans, appears to be quite permanent. It has been observed many years after the original focal infection and period of hemorrhage.

The development of such masses of white fibrous tissue generally, perhaps always, follows hemorrhage. Hemorrhage is at first quite absent from these retinal lesions, although in most cases the loss of vision caused by hemorrhage is the first thing that brings the patient under observation. This is extremely interesting when we remember the long controversy in which many famous names were marshaled in support of the view that hemoptysis was the cause of phthisis. It seems always to be present in cases of retinal tuberculosis; and it is probable that in a majority of cases, massive hemorrhage occurs, arresting attention by great reduction of vision.

The hemorrhage is first observed several days or weeks after the first retinal lesion. In Finnoff's case, which was seen very early on account of corneal lesions

and eye strain, the first hemorrhage was found at about the fourth week. From the time they begin they continue to recur so long as the disease remains active, often for many months or years. The tendency to the formation of white fibrous tissue is closely connected with the occurrence of relatively large hemorrhages. Hemorrhage, so far from being the cause of the disease, is one of the defensive resources of the organism, although very disastrous to sight when occurring in this situation. I have twice seen it occur within forty-eight hours after therapeutic subcutaneous doses of tuberculin.

The focus of infection may occur in any part of the eye. In the skin of the lids it has the varied characters of lupus, and in the conjunctiva almost as wide a variety. In both of these structures the lesion is apt to depart rather widely from the typical tubercle; both here and in tuberculosis of the lacrimal passages it is generally difficult, and sometimes impossible, to distinguish the bacillus by the usual staining methods. I would suggest that in these lesions the search be carried on with the help of other than the Ziehl stain. In the cornea, a nonvascular tissue, tuberculosis generally appears as an extension from the anterior chamber, iris or ciliary body. Occasionally the focus has seemed to be originally in the substance of the optic nerve, although much more commonly in the neural sheaths.

UNRECOGNIZED TUBERCULOUS INFECTIONS

From what has been observed in the eye, the part of the body most completely open to observation, the statement seems justified that the tuberculous focus of infection may be found, and may first attract attention, in any organ or tissue of the body. This is generally admitted. What is not generally appreciated is the fact that tuberculous focal infections do occur and pass unrecognized in other parts of the body more frequently than they do in the lungs, lymph glands, spine and hip joint, where they are generally recognized.

The great obstacle to the recognition of a tuberculous focal infection where we are not looking for it has been the fact that there was no tuberculosis where we expected to find it. In one case of ocular tuberculosis, failure to react to tuberculin tests and the absence of any signs of the disease in lungs, bones, joints or notably enlarged glands was supposed by a competent internist to rule out tuberculosis. But a few months later the opening of the skull for organic brain disease revealed a tuberculous meningitis. The diagnostic use of tuberculin is known to fail us sometimes in pulmonary and general miliary tuberculosis. We must admit that its negative showings do not rule out a tuberculous focus of infection in some other part of the body, where such a focus would be less likely to be thought of.

It may be that Naegeli's statistics, showing that, up to the age of 18, 97 per cent. of all persons coming to necropsy have suffered from some focus of tuberculous infection, do not apply generally, and exaggerate the prevalence of such infections. However, only a belief in some such prevalence will eliminate a large number of errors of diagnosis in the direction of failure to recognize such lesions.

When, a few years ago, I had tuberculin given for a chronic choroidal lesion, the reaction of pain and swelling in the metatarsophalangeal joint of the great toe helped to confirm the diagnosis; it revealed a lesion that otherwise would have escaped attention, or its

significance would never have been thought of by the patient. Probably this "confirmation" would have left the diagnosis of tuberculosis subject to a great deal of skepticism on the part of doubting colleagues. But such skepticism would hardly have stood up against the severe tuberculous pleurisy that this patient developed with a new focus in the choroid six years later.

My experiences with tuberculosis have disposed me to look widely for its foci of infection, and accept its great chronicity and prolonged latency or arrest. A woman was supposed to have phthisis in her early twenties, and early death was anticipated. One of her brothers and a sister had died of the disease. But her husband, a farmer, got her a horse and buggy which were always kept for her own use. She scandalized her country neighbors by the amount of time she spent driving about. She always had a cough; and when she died at over 75 years of age, necropsy revealed cavities, calcareous and cheesy nodules, and other foci which were active.

Early in my general practice, I assisted at a necropsy of a patient who died of phthisis; the attending physician explained to us that he expected to find in one kidney the evidence of a tuberculous infection that he had diagnosed as a kidney lesion more than twenty years before. We found there the calcareous and cheesy masses, with active tubercles. Another patient had suffered and apparently recovered from a tuberculous pleurisy ten years before the onset of discoverable pulmonary symptoms that ended three years later in death from phthisis. If there is one lesson of my professional life that stands out more strongly than any other, and which seems to deserve all the emphasis that can possibly be put on it, it is that an enormous number of tuberculous focal infections occur in persons not considered tuberculous by themselves, their friends, or even their physicians.

Perhaps not every one is tuberculous; but successful diagnosis requires that every one presenting symptoms which might arise from a tuberculous focal infection should be assumed tuberculous until the contrary is proved. Above all, we must get away from the error of letting family history, recent exposure, favorable conditions of life, or apparent recent health, influence our judgment of the probabilities of the existence of a focus of tuberculous infection somewhere within the body. All these things are invoked to prove that a lesion is not tuberculous; and they all tend to prevent the recognition of unusual or minor infections.

PATH OF INFECTION

Some very practical points are connected with this conception of tuberculosis as a focal infection. It has often been asked whether the lesion was primary or secondary, and on the answer to this it was sought to decide the plan of treatment. Excision of tuberculous foci in glands, bones, conjunctiva or eyeball has been fairly tried, sometimes with results a little better than those of nonoperative treatment, but in some cases with results distinctly worse.

There has been at times, and in certain people, an almost hysterical fear of the "contagiousness" of consumption, leading to folly and inhumanity in the treatment of those manifestly suffering from phthisis. Health regulations have been ruthlessly enforced by officials who carried in their own persons the active lesions or the latent focal infections of tuberculosis. Such fear and such regulations have been based on

suppositions regarding the channels by which tuberculosis is usually transmitted and enters the human body.

When we come to examine the facts, it becomes evident that we know very little about the path of infection. Two portals of entry have received much attention, the respiratory tract and the alimentary canal. But the facts that stand prominently forth in all the accumulated literature are: The tubercle bacillus gets entrance to the body usually long before any of the effects of its presence are recognizable, and often makes itself known first in the interior of the eye, in the head of the femur, or the bodies of the vertebrae. It has been known to enter the body without giving the slightest evidence at the point of entrance.

Possibly when the first manifestations are in a chain of lymph glands, as in the neck or mesentery, these point correctly to the portal of entry. But at the point of entrance there is no evidence of disease; primary tuberculosis of the tonsils or of the mucous lining of the intestine is of extreme rarity. In the great mass of cases the involvement of these surfaces is manifestly late and secondary.

Even in the lungs the evidence of lesion at the point of entrance is contradictory and inconclusive. In the human being, pulmonary tuberculosis is always discovered after the essential lesion has reached an advanced stage of evolution; or it is recognized after the lesion has run its course, broken down and is discharging bacilli. In animal experimentation there are great gaps between the inhalation of the bacilli, and the finding of lesions in the lung. With lupus, in many respects an aberrant form of tuberculosis, the beginning and course of the lesions ally it with internal focal infections rather than suggest that it is an initial lesion.

Only in the wartlike lesions that follow slight injuries to the hands of postmortem workers, and a few cases of tuberculosis of the conjunctiva, is the preponderance of evidence in favor of lesion at the site of entrance. There is just one case on record of tuberculous ulcer of the cornea following lesion from the nail of a tuberculous child.

The evidence we now have indicates that the point of entrance plays little part in determining the location of the primary focus of infection, unless possibly when this is some lymph gland. The bacilli find their way into the circulation without provoking reaction; and in some favorable situation, some point of lowered resistance, establish a colony, a focus of infection. The possibility of the development of such a lesion, and of its subsequent power for extension and general harm, lies in insufficient resistance of the body tissues.

IMMUNITY

The great majority of human beings, at least those living under the conditions of civilization, harbor tubercle bacilli at some time in their lives, just as every country that has attained a social organization harbors anarchists. It may be wise and right to reduce and keep down the infection to a minimum. But for the mass of us the only effective defense that stands between health and a generalized, acute miliary tuberculosis is a certain amount of tissue resistance, of tissue immunity; and it is toward understanding and building up this resistance that the war on tuberculosis must be more and more directed, if it is to be successful.

Some things we know about it: the value of outdoor living, sunshine, rest, alimentation, a cheerful disposition toward the events of life, the value of injecting a specific provoker (tuberculin), when this is not

furnished in sufficient quantity by the focus of infection. But surely there is a great deal more to be learned about this immunity; there is an immense field of labor for the medical profession, in forcing on the community the importance of the facts about it that we already know, and it is the duty of our civilization to see that by legal enactment, by social custom, by individual example, by universal teaching in our educational system, our knowledge is applied in the life of the people.

CONCLUSIONS

Briefly, we have learned that:

The different forms of this focal infection are one disease—the unity of tuberculosis.

A very large proportion of those who suffer such infections never suffer the conditions that were formerly recognized as tuberculous—phthisis, scrofula, bone disease, etc.

At its point of entrance, the tubercle bacillus very rarely provokes any reaction or excites a noticeable lesion.

Foci of infection are established within the bodies of a great many people, where they are kept in check by tissue resistance.

A MODIFIED TECHNIC IN OPERATION FOR OBLIQUE INGUINAL HERNIA

WILLIAM A. ANGWIN, M.Sc., M.D.

Commander, M. C., U. S. Navy

GREAT LAKES, ILL.

This modification of standard technic for the operative cure of oblique inguinal hernia has been developed over a period of time. It is a product of gradual evolution, in which the basic features are classical; but by a successive adaptation and combination of features that in my experience and observation have been found desirable, the classic has undergone changes and variations. The results have proved quite uniformly successful and satisfactory.

DETAILS OF TECHNIC

STEP 1.—After the patient comes to the operating table, the site of the operation is twice painted with 5 per cent. picric acid in 95 per cent. alcohol. The landmarks of the operative field are located: the anterior superior spine of the ilium, pubic spine, middle of the base of the penis, Poupart's ligament, and the external inguinal ring. An

Fig. 1.—Exposure of aponeurosis of left external oblique, showing line of incision not entering the external ring. Ilio-inguinal nerve emerging through external ring.

Fig. 2.—Incision has been made in aponeurosis, exposing internal oblique muscle, cord and ilio-inguinal nerve.

Fig. 3.—The internal oblique and transversalis muscles have been pulled upward, and peritoneum is caught with forceps; cord not disturbed.

The overcoming of tuberculosis is chiefly a matter of building up and sustaining immunity by wise and careful living.

Resolutions on Use of Vaccines in Influenza.—At a meeting of the sanitation committee of the Allegheny County Medical Society, a resolution was adopted to cooperate to the fullest extent with the Department of Public Health of Pittsburgh with whose action this committee is in complete accord. Another resolution provided that the committee indorse a request suggested by Major Davis that all physicians in the city of Pittsburgh report their cases of influenza. The committee announces its position with reference to the use of prophylactic vaccine in connection with the present possible epidemic of influenza as follows: 1. There is no evidence to show that any of the so-called prophylactic vaccines which have been used will prevent influenza. 2. No physician or other person has a right from the data on hand to guarantee protection to any individual because of the administration of a prophylactic vaccine for influenza or pneumonia. 3. It is possible that the antipneumococcus vaccine has value in the prevention of pneumonia. 4. Prophylactic vaccination to be protective should be completed before exposure to the disease.—*Bulletin Allegheny County (Pa.) Medical Society.*

incision is made through the skin and superficial fascia parallel to and about three-fourths inch above Poupart's ligament, extending from the external ring upward and out to about one inch beyond midline of Poupart's ligament. Superficial vessels are caught up and ligated. Vessels liable to be severed are the superficial epigastric and superficial external pudic arteries and veins. This incision exposes the aponeurosis of the external oblique and the external ring (Fig. 1). The aponeurosis should be well cleaned by wiping back the superficial tissues to Poupart's ligament below and about 1¼ inches above the incision. Care must be taken not to injure the ilio-inguinal nerve, which sometimes emerges through the aponeurosis above the external ring. The wound is thoroughly dried before the next step.

STEP 2.—An incision is made through the aponeurosis of the external oblique muscle, beginning about one-fourth inch above the external ring and continuing upward in the direction of the fibers of the aponeurosis or slightly across them toward Poupart's ligament to a point just beyond the internal ring (Fig. 2). By cutting slightly diagonally across the fibers, the exposure of underlying structures is facilitated. With the handle of the knife the inside of the aponeurosis is cleared first downward along the shelf of Poupart's ligament from the internal ring to the pubic spine, then upward exposing the internal oblique muscle, the internal ring, the conjoined tendon and the sheath of the rectus. Care must be taken not to injure the ilio-inguinal nerve

lying either along the cord or on the internal oblique muscle, or the iliohypogastric nerve which sometimes comes through the internal oblique muscle low down. Generally it is found in the upper external angle of the wound (Fig. 6).

STEP 3.—The handle of the knife is then placed between the conjoined tendon and the cord, and separates those structures and the muscles up to the internal ring.

STEP 4.—The internal oblique and transversalis are put on the stretch and a retractor is inserted to pull those muscles upward, exposing the peritoneum above the internal ring. This frequently bulges like a sac (Fig. 3).

Fig. 4.—The peritoneum has been incised; the finger enters the sac from above downward; neck of sac is about at crook of finger.

Fig. 5.—Sac being tied off well above neck, above incision in peritoneum. (This illustration represents a very small sac which has been split to its tip.)

Fig. 6.—Dislocation upward of ligated peritoneal opening. The iliohypogastric nerve is shown in the upper angle of the wound lying on the internal oblique; it is frequently injured by suturing.

STEP 5.—The peritoneum is caught up and incised between two forceps. This incision is made in the peritoneum proper above the neck of the hernial sac, which can now be located by viewing it from above and by the insertion of a finger into the sac. This one step has greatly facilitated the search for the sac; in fact, no search is needed.

STEP 6.—The finger is inserted into the sac from above, and the sac is freed from surrounding tissues by gauze dissection (Fig. 4).

STEP 7.—The sac is then ligated by transfixion in the usual manner, but the ligature surrounds the opening in the

STEP 9.—The free borders of the internal oblique and the transversalis are caught together in two forceps and turned upward, exposing the posterior surfaces of these muscles, to which is sewn, at about three-fourths inch from the free border, the upper edge of the cremaster muscle, continuous small plain catgut being used (Fig. 7). This covers the cord down to a new ring just above the spine of the pubes. One should avoid catching the ilio-inguinal nerve in this suture.

STEP 10.—The free borders of the internal oblique and transversalis muscles and the conjoined tendon—are now

united to the shelving portion of Poupart's ligament by chromic catgut or kangaroo tendon, substantial bites of the muscle being taken (Fig. 8). The sutures are tied without undue tension. The cord emerges over the pubic bone beneath the lowest suture. The two nerves mentioned should be avoided; frequently the iliohypogastric is quite low enough to be caught. The lowest suture should also include the external edge of the sheath of the rectus for strength, especially when the conjoined tendon is defective.

STEP 11.—The aponeurosis of the external oblique is brought together with plain catgut, if necessary, reinforced by imbrication. The external ring has not been molested. It is sometimes advisable to make it smaller by one or two sutures.

STEP 12.—The superficial tissues are closed by any of the usual methods.

Fig. 7.—Free borders of the internal oblique and transversalis muscles are caught together and everted, exposing posterior surface; upper edge of cremaster is sutured to posterior surface of transversalis about three-fourths inch from the border; the cord is buried beneath the cremaster.

Fig. 8.—Free borders of internal oblique and transversalis muscles are sutured to shelf of Poupart's ligament.

peritoneum, thus insuring absolutely the removal of every vestige of the sac (Fig. 5).

STEP 8.—The neck of the sac, or rather the pucker of peritoneum, is dislocated upward beneath the internal oblique and transversalis, the ends of the tie-off ligature being passed through those muscles about three-fourths inch above the internal ring (Fig. 6). The cord has not been disturbed nor removed from its bed.

ADVANTAGES OF THE TECHNIC

This method results in:

1. Easy and unmistakable location of the sac.
2. Assurance of the absolute removal of the entire sac *well above its neck*.
3. Removal of peritoneal pucker from the area of weakness by dislocating it upward beneath solid muscle.
4. Strong repair of the muscular and aponeurotic coverings.

U. S. Naval Hospital.

Keep the Farmer Well.—A large part of the land in the richest sections of the South, and to a less extent in the North as well, is today partially or wholly unproductive on account of being overrun with malaria, with a consequent loss of millions of dollars. Every case of malaria or other efficiency reducing disease means that the output of food is appreciably reduced and that the shortage is immeasurably increased.—*Bulletin*, State Board of Health of Rhode Island, August, 1919.

SPINA BIFIDA OCCULTA IN A CHILD
WITH INCONTINENCE OF URINE
AND FECESIMPROVEMENT IN VESICAL CONTROL AFTER
OPERATION *

JEROME S. LEOPOLD, M.D.

NEW YORK

The great majority of cases of spina bifida occulta have been noted in early adult life; its presence in childhood is uncommon enough to warrant the publication of a report of an instance that came under my observation.

According to Brickner,¹ "spina bifida means bifid spine, and that individual has a spina bifida who has a cleft in the spine whether or not there is a protrusion of the spinal structures." The term "spina bifida occulta" was first employed by Virchow in 1875, when he reported a case of spina bifida with the lesion concealed beneath the skin.

Since reading Brickner's article it has been our routine procedure to have roentgen-ray examinations made of the spine in all children presenting partial or complete incontinence of urine. As a result, the positive diagnosis in the case here reported was promptly arrived at. It is our firm conviction that not a few cases of enuresis in children are due to spina bifida occulta.

REPORT OF CASE

History.—E. F., girl, aged 6 years, admitted to the A. Jacobi Division for Children of the Lenox Hill Hospital, May 1, 1919, was born after normal labor, birth weight unknown. She was artificially fed; the first tooth appeared at 7 months. The patient talked and walked when 1 year old. She had had varicella and measles, and had always been irritable and "nervous." Eight months before the tonsils and adenoids had been removed. An older brother had had chorea, and had always been irritable, and now had nocturnal enuresis. The mother was poorly developed and of a nervous temperament. She had had no miscarriages. The father had syphilis ten years before (four years before the birth of our patient) for which he received treatment at this hospital.

The present illness started about one year prior to admission, when the patient was 5 years old. She began to lose bladder control at various times. Interference with vesical function gradually became more constant, and was soon accompanied by rectal incontinence. These symptoms became progressively worse, so that at the time of admission to the hospital there was almost complete loss of control both of the bladder and the rectum. There had been no remissions or intermissions. The patient had suffered no injury, nor was there a history of any illness to which the present complaint could be referred. The child was well advanced at school, and played and talked with other children in a normal fashion.

Examination.—On admission to the hospital, the child was fairly well developed, weighed 36 pounds, and the general condition was good. The general physical examination was negative.

Nervous system: The knee jerks were very active. There was no ankle clonus, and no Babinski phenomenon nor other abnormal reflexes. The superficial abdominal reflexes were present. No sensory and no motor disturbances were discovered after a very thorough examination, in which the patient coordinated well.

Back: There was a fairly well marked, compensated left lateral scoliosis with some asymmetry of the left chest-wall,

posteriorly. Over the upper part of the right buttock, just to one side of the median line, there was a small blind pocket or dimpling of the skin. Hypertrichosis, often associated with spina bifida occulta, was absent. There were no trophic disturbances.

The Wassermann reaction of the blood and the Schick test were negative. The von Pirquet reaction was positive. The urine was negative. The blood examination on admission was: white cells, 8,000; polymorphonuclears, 40 per cent., and lymphocytes, 60 per cent.

Roentgen-ray examination by Dr. W. H. Stewart disclosed a typical spina bifida, the upper arches of the sacrum being lacking, as shown in the accompanying illustration.

The chief points of interest in this case were: (1) the history of one year's duration of loss of bladder and rectal control; (2) the blind pocket or dimple in the skin over the sacrum, and (3) the positive roentgen-ray findings.

The history of incontinence together with the presence of a small dimple in the skin just over the sacrum made us very certain that we were dealing with a case

Spina bifida of the sacrum, with a distinct cleft in the first sacral arch and the absence of the remaining sacral arches.

of spina bifida occulta. The roentgen-ray examination, which showed a distinct cleft in the first sacral arch and the absence of the remaining sacral arches, confirmed the diagnosis.

According to C. H. Frazier,² symptoms in spina bifida occulta may be present at birth, but more often they do not appear until early adult life, when the membranous band between the cord and the epidermis begins to compress or pull on the cord and nerve roots. There may be present motor, sensory or trophic disturbances in the lower extremities. Incontinence of the bladder and rectum are often present. At times there are defects and malformations in other parts of the body.

In this connection it may be of interest to mention that Brickner divides cases of spina bifida occulta into these groups: (1) with external signs and with symptoms; (2) with external signs without symptoms; (3) without external signs with symptoms, and (4) with-

* From the A. Jacobi Division for Children of the Lenox Hill Hospital.

1. Brickner, W. M.: *Am. J. M. Sc.* 155: 473 (April) 1918.

out external signs without symptoms. According to this classification, our patient comes under Group 1, since there were present external signs (dimple) with symptoms of incontinence.

In some reported cases of spina bifida occulta with symptoms of disturbed sphincteric control, and in others with severe trophic disturbances in which lipomatous tumors and hernias of the cauda equina were found, operative procedures have been of great benefit. At times, simple separation of the membranous bands between the cord and epidermis has resulted in relief of all symptoms.

Course and Treatment.—During a period of three weeks' observation in the hospital, the patient manifested loss of bladder and rectal control, practically daily. In view of the fact that the disturbed sphincteric control had been increasing progressively during the year's illness, an exploratory operation seemed advisable. Accordingly, three weeks after admission to the hospital, operation was performed by Drs. Willy Meyer and W. M. Brickner. A semicircular incision was made through the skin and subcutaneous tissue over the sacral region. The incision started at the level of the first sacral vertebra, curved to the right, and ended at the last sacral vertebra, so that the concavity was toward the median line. The skin flap was reflected, and the incision was extended upward in the right paravertebral line to the last lumbar vertebra. The fascia over the sacral ligaments was divided in the median line and retracted. A small amount of fatty tissue was removed from the field. Examination then revealed the cleft in the laminal arch of the first sacral vertebra. Furthermore, the remaining sacral arches were practically absent, the defect increasing in diameter as the exposure was extended toward the anus. The operative field consisted of a view of the posterior aspect of the body of the sacrum, the sacral canal being exposed to view.

The laminal arch of the fifth lumbar vertebra was resected with bone forceps to obtain better exposure. No advantage was gained by this procedure, as the spinal canal ended at the fifth lumbar-first sacral intervertebral space, and it was decided that to open the spinal canal would be of no avail. The condition was judged to be beyond surgical relief. The fascia was sutured with chromic cutgut, the subcutaneous layers were sutured with plain gut suture, and the skin was closed with silkworm gut.

The findings at operation corroborated the roentgen-ray examination in a very precise manner. While the bony defect was easily recognizable, the nerve lesion, if there was such, was not discovered.

In this case there was no hernia of the cauda equina, and no fatty tumor.

Postoperative Course.—During the four weeks following operation, while the patient remained in the hospital, there was no incontinence of urine or feces. She was then sent home, and for one week she had complete control of the rectum and bladder. After that period, however, she lost control of the rectum, and this condition has persisted up to the last report, which was five months after the operation. For some unexplained reason, however, the patient since operation has retained full control of the bladder function.

In view of the operative findings, it is difficult to see how the operation could have had any effect. One can only advance the suggestion that possibly the fixed scarlike dimple in the skin over the bifid spine resulted in a tug on the membranous posterior wall of the sacral canal and thereby affected some of the roots of the cauda equina concerned with vesical function. If this was so, the separation of this puckered area from the underlying sacral canal, as carried out at operation, may have had the described effect on bladder control.

701 Madison Avenue.

MESENTERIC, OR ENTEROGENOUS, CYST

CHARLES STANLEY WHITE, M.D.

WASHINGTON, D. C.

The infrequency of the mesenteric, or enterogenous, cyst and the obscurity of the symptoms are indicated by citing the statement of Miller,¹ that but thirty-five cases were reported up to 1913, and in none of the cases was the diagnosis made prior to operation or necropsy.

The etiology remains clouded, diverse views still obtaining, chiefly expressed as dilatations of mesenteric lymphatics and sequestration of the enteric canal. Briefly stated, the histologic characters differ somewhat; the cyst wall is devoid of mucous membrane in several of the reported cases, and these have fostered the opinion that the growth is entirely mesenteric. In the majority, however, the lining of the cyst bears a close resemblance to the epithelium of the intestine, even to the extent of containing villi and muscle fibers. The tumor is invariably congenital and situated at the mesenteric attachment of the small intestine. By some it is believed to be an erratic development of Meckel's diverticulum.

The symptoms are those of a movable tumor or intestinal obstruction and frequently an amalgamation

Fig. 1.—Intimate relation of cyst to intestine.

of the two entities, and it is because of its protean characteristics that the proper interpretation of the symptoms is not easy. So frank are its manifestations of obstruction that any other diagnosis is impossible in some instances, while, on the other hand, a movable tumor in any quadrant of the abdomen forces the conclusion that we are dealing with a floating kidney,

1. Miller: Bull. Johns Hopkins Hosp. 24: 316, 1913.

ovarian cyst, enlarged gallbladder or pedunculated uterine tumor. So variable are the symptoms that few remain which are pathognomonic.

REPORT OF CASE

A boy, aged 4 years, was first seen in December, 1914, and at this time no diagnosis was made. Dr. E. P. Copeland

Fig. 2.—Cyst detached.

assumed charge of the patient and later reported the case.² It is with his permission that the following paragraphs are incorporated here:

"In December, 1914, approximately a year before my first examination, the patient became suddenly ill in the night, with an attack characterized by extreme nausea and severe vomiting and the appearance of a rounded tumor in the hypogastrium, simulating a distended bladder. The vomiting, to judge from the description, was simply bile-stained gastric juice and at no time stercoraceous. The tumor was elastic, but not especially tender to touch. There was no history of previous disturbance in the regularity of the bowel, as to constipation or diarrhea. Fever was not present.

"The physician called at the time had evidently made a diagnosis of intussusception and had completed plans for an immediate removal to the hospital for operation. Returning a few hours later for the patient, he had been, as could be well imagined, much surprised to find that the mass had spontaneously disappeared and the patient recovered.

"After this initial appearance, these attacks had recurred at varying intervals, seldom less than three weeks and on several occasions as long as six weeks. They had varied in the severity of associated symptoms and likewise in duration, seldom, however, lasting over two days. The tumor had invariably appeared first over the region of the bladder, sometimes larger, sometimes smaller, moved about the abdomen spontaneously, and finally disappeared. Its appearance had always been associated with nausea and vomiting, and its disappear-

ance with a pronounced paroxysm of abdominal pain. Following the first attack there had been some tendency to constipation, but the bowels had been kept freely open by the daily employment of mineral oil by mouth. The diet had been well regulated, and in the intervals the patient had quickly recovered lost weight. Ordinarily the child was quite normal, played actively, and appeared in good health. No prodromal symptoms had been observed.

"At the time of the first examination, I found the patient in bed lying on his back, thighs partially flexed. The attack was several hours old, and there was still some nausea. Presenting in the hypogastrium was a smooth tumor about the size of an orange, elastic, but not tender to touch, and dull on percussion. It was palpable by rectal examination and suggested strongly a distended bladder. The mass was, however, freely movable, it being possible, without undue force, to manipulate it about the entire abdomen. There was a fairly well-pronounced beading of the ribs. The pulse rate was rapid, but regular. The temperature normal. A leukocyte count gave 11,500. The von Pirquet and Wassermann tests were negative. No further significant facts were observed.

"Under restricted feeding and large enemas slowly administered, the mass spontaneously disappeared. An examination of the abdomen subsequently was absolutely negative."

The roentgenologist made an exhaustive roentgen-ray study, and concludes his report in this manner:

"Finding: A tumor mass the size of a large orange is palpated in the right upper quadrant. The bismuth injection showed the mass to be redundant descending colon. Visualized palpation reduced the tumor."

Dr. William Gerry Morgan, in March, 1917, examined the patient and found a movable tumor, with intermittent attacks of intestinal obstruction. At this time the hemoglobin was 83; red cells, 5,950,000; white cells, 11,600; polymorphonuclears, 67.5 per cent.; lymphocytes, 18 per cent. The urine contained albumin, indican, urea, 3 per cent., casts and excess of urates.

Dr. Francis Hagner saw the child in consultation, and suggested a possible cyst of the urachus.

On operation, April 4, 1917, an enterogenous tumor of the ileum was found about the size of a baseball. It was impos-

Fig. 3.—Interior of cyst.

sible to shell it out, and the only feasible operation was resection of the bowel. The child made a smooth recovery and has been well since.

Dr Lindsay reported as follows:

"Large cyst with membranous attachment, taken from the mesentery. On gross section, wall of cyst and mesentery have thickness of 0.5 cm. Cyst wall resembles similar sections of thickened intestine or stomach wall. There is a blood clot adherent to the wall internally directly opposite

2. Acker, G. N., and Copeland, E. P.: Transient Abdominal Tumor in a Child of Five Years with Redundant Colon, *Am. J. Dis. Child.* 12: 602 (Dec.) 1916.

the mesenteric attachment. Sections in regions of blood clot show muscular and fibrous tissue with a hemorrhagic area corresponding to the clot. The surface is covered with a layer of fibrin containing blood cells and a narrow layer at one point in outline resembling the intestinal mucous membrane, though gland elements are not present. Sections at region of mesenteric attachment show quite well preserved layer of mucous membrane, long villi and deep crypts being definitely recognized. Beneath this is a layer of muscle. None of the sections show evidence of malignancy."

COMMENT

The symptoms were consistent with the conditions found at operation. The tumor, while not communicating with the intestinal canal, probably varied in size at times owing to the torsion produced on either side when it rotated on an axis parallel with the intestine; and the same torsion was responsible for the enteric obstruction. It may well be compared to a hammock which had been turned over, twisting its supporting ropes.

The conspicuous and significant symptoms were the resilient, freely movable tumor with intestinal obstruction.

Fig. 4.—Relative thickness of cyst wall.

tion of an intermittent type, a low leukocyte count, sudden onset and rapid recovery in each attack, and the age of the patient, 6 years. The roentgen ray was of no aid, but on the contrary was misleading, as the dilated colon noted in the roentgenologist's report was undoubtedly small intestine, filled by bismuth through an incompetent ileocecal valve.

Cleansing Arsphenamin Apparatus.—DR. JOHN B. DONALDSON, Lorain, Ohio, writes: After giving arsphenamin or neo-arsphenamin injections I always disconnect the rubber tubing and run hot water through it for a few minutes as well as washing the glassware; but I have noticed that if the connected outfit is allowed to stand with distilled water in the arsphenamin side, quite a yellow tinge develops in the water. This indicates that there may be sufficient arsphenamin or neo-arsphenamin in the container and tubing to decompose and produce a toxic reaction at the next administration unless thorough washing is done. I have recently run sterile distilled water through the outfit before using as an extra precaution. It is to be inferred that we clean the intravenous outfit before sterilizing it; but the point I wish to bring out is that the thoroughness with which it is done is more necessary than I had supposed.

THE MYENTERIC NERVE NET

A DISCUSSION

G. K. DICKINSON, M.D.

JERSEY CITY, N. J.

From biologic studies it must be inferred that the sole reason for life—vegetable, animal and human—is to continue the species, and that man's superior brain and body are for the purpose of better protecting the germ plasm as well as for social life, the pleasure of work and the joy of mental effort. We worship the mind and its products, and outwardly we suppress the instincts begotten by Nature. We might be deprived of all but the essentials, circulation, digestion and reproduction, and yet maintain the race as do the lower animals. Man lives but to propagate.

These primitive essentials, all important for life and its perpetuation, are carefully secluded and separated from the outward man, which is under the control of a wilful and highly developed nervous system: such intercommunication as exists being entirely beyond the control of the mind. The actions and functions of these three sets of organs are largely autonomic, and in the history of all time it is noted that they are the oldest.

The biology of the kinetic systems of the heart and genitalia have been well stated, but not that of the enteric system.

EMBRYOLOGY OF ENTERIC SYSTEM

About the end of the second week after fecundation, the first evidence of the stomach is found, the development of the intestine following out a definite plan of evolution. As in early life we have the stomach without the intestine, so in early fetal life we have the stomach first; then from it extends progressively the intestinal tube down to meet the hindgut. It has been evolving since the beginning of life and has felt the influence of conditions which tend to modify as well as create, so that the digestive apparatus, as a result of evolution, is the simplest and most perfect, the tissues entering into its structure being still primitive. Evolution invariably develops simplicity of structure and function in the end; and in this instance there is no exception, but a wonderful demonstration of the relation of simple tissue to the essential needs of a highly developed animal.

In the 10 mm. embryo the circular muscular layer of the intestine is first demonstrated, the longitudinal layer appearing in the 75 mm. embryo. Between these two layers from the mesenchyme is developed a syncytium out of which further develops the intestinal tract. On the inner side can be seen the spindle cell muscle extending to the circular layer, and on the outer side similar cells extending to the longitudinal layer. In this mesenchyme develop all the other tissues which go to form the structure of the intestinal wall: blood vessels, lymphatics, fibrous tissue and nerve net.

Early in embryonal life there bud out ventrally from the spinal ganglions prolongations which become the sympathetic plexus. From it, cells migrate farther inward to the intestinal tract to enter its structure. From the hind brain (the intestine being close to it in early life) there wanders a nerve which also passes to the intestine and through its walls, terminating in numerous gray ganglions approximated to the longi-

tudinal layer. Because of the wanderings of this nervous structure it is later called the vagus.

As the intestine grows from above downward, it passes by an accumulation of nonstriated fibers, which eventually go to the skin and subdermal tissues. Part of this dermal muscular mass is picked up by the intestine and carried down with it, later to be found at the three sphincter points: pylorus, ileocecal and internal anus.

We have a third type of muscular tissue developed in the intestinal tract. To understand it, we must go back again to biology. In the nine months during which the egg grows into the mature child, all the changes and steps which life has undergone in eons are recapitulated. Morphologically and histologically, we see in the developing fetus much that can be found in the lower forms of life; and by studying low life we often come to a better understanding of conditions in the human.

In the sponge, we have evidence of muscular action. The microscope discovers no nerve tissue, but a muscle cell which is neuromuscular, having the properties of irritability, contractility and conductivity. It will receive an impression, contract, and call on neighboring muscular tissue also to contract. In forms higher up, such as the anemone and starfish, we find end organs which receive impressions and filaments that look like nerves running to the muscular cell. Somewhat higher in the scale we find ganglions, so that we have a nerve ganglion connected with muscle resulting in more efficient action. This type of nerve is called neuroid.

From the processes of development and from microscopic demonstrations one would judge that the neuroid fibers developed from the muscular. Certainly with this type of muscular tissue there is a great deal in common. Keith has discovered in the intestinal tract this primitive type of neuromuscle, particularly noticeable at points of polarization: the cardiac end of the stomach, pylorus, ileocecal region and large intestine. This neuromuscular tissue is difficult to differentiate from nerve tissue.

Through the entire intestinal tract, from the beginning of the smooth fiber muscles in the esophagus to the rectum, we find a definite close mesh of what has been called nervous tissue, discovered by Auerbach and named for him. It is slender, flattened, covered by endothelial membrane and connected with the ganglions which are the termination of the pneumogastric and the terminal filaments of the sympathetic nerves. It is also connected with the neuromuscular tissue of Keith.

The deductions from Keith's work are that this plexus, or nerve net, is really a modified muscular tissue, a syncytium retaining its connections from early embryonal life, that it developed in the mesenchyme and from the mesenchyme, that it did not migrate in with the sympathetic nor with the pneumogastric nerve, and that it differs from other nervous tissue histologically, chemically, embryologically, biologically, and in innervation and staining properties.

It is analogous, if not similar, to the nerve net of the heart, which is connected with and activated by the sinu-auricular node and the bundle of His, which we know stimulate the heart action through the Purkinje fibers.

It can be seen that in the intestinal tract we have developed conditions which will permit of slow and

conservative adjustment to the vegetative processes demanded of it; that we have three types of muscular tissue which are serving a different purpose, three types of nervous tissue, all coordinating and cooperating, yet independent.

PHYSIOLOGY OF THE INTESTINE

The physiology of the intestine is that of its component parts. We have, as stated before, three types of smooth muscular cells in the body, and chemically and embryologically we note the difference. In the skin, in the structures which have developed from the wolffian body and the duct of Mueller, and in the sphincters of the intestine, we have the dermal type; in the remainder of the intestine, in the heart and in the spleen, the second type; and in the neuromuscular tissue of Keith, the third. All of these have different biologic properties and physiologic actions.

All cell activity is maintained by the electrolytes circulating in the blood. The sodium in particular has the property of developing electrical forces, especially in the type of muscle cell we have under consideration. The calcium electrolyte controls the effect of the sodium salt, if too active. The several muscle cells react differently to this physicochemical process, and all tissue of this type is constantly contracting and relaxing as a result of this stimulation. It is termed embryonal because early in embryonal life, before there is any nerve tissue formed, the primitive muscle cells are contracting and relaxing. This is seen in the cardiac tube and in the primitive stomach, and biologically we find the same conditions existing in lower forms of life.

As the content of the stomach, acid in reaction, passes into the duodenum and encounters an alkaline fluid, it effervesces and becomes frothy. This increases the amount of distention and acts as an irritant to the muscle cell. Myogenic contractions occur, contractions which are independent even of the nerve net. They are slow, not forceful, and do not produce marked anemia of the substance. Then there is gentle relaxation; this process is repeated until apparently fatigue of muscle ensues; then it stops and is taken up elsewhere in the intestinal tract. This is the rhythmic movement of the physiologist. If the distention is greater, the nerve net is called into action and we have initiated the peristaltic wave, first noted by Cannon and best explained by Sherrington. In the body, when the flexor muscle is called on for action, there is an inhibitory effect thrown on the extensor in order that the flexor may act. This is true also in the intestine. If a contraction is to be instituted in any part, induced by the net, as the flow of nerve energy is always peripheral, toward the anus, there will be a relaxation of the muscles distal to the point of contraction, thus enabling the intestinal content to be more easily pushed forward.

There are times when not only the circular but also the longitudinal fibers are brought into action. This produces a peculiar motion which is termed the pendulum. The neuromuscular cells are pace makers and tonus givers. Contractility is not their only function. They serve better to transform nerve energy into muscle action at certain points. The tonus just distal to each point of polarization in this type of muscle cell is always increased. Irritability and contractility are greater. Peristaltic waves are more pronounced. A section removed from the duodenum or upper ileum

shortens itself and curls over on the edges more than a section taken farther down. Placed in proper fluid, it will retain its rhythmic contractions much longer.

In the upper intestinal tract it is a wise provision, because there the enzymes are abundant and imperfectly mixed and proper digestion and chemical changes cannot occur. The tonus is poor in the lower part of the intestine in order that there may be delay and sufficient absorption of the chyme before it passes over into the large intestine.

The tonus of the large intestine is produced by the polarization of the terminal ileum. In all animals, particularly in those that eat vegetables, the cecum has a direct ratio to the stomach in importance. It is here, in the colon, that we have instituted absorption of fluids which control dehydration and calcium metabolism. The appendix as well as the cecum is highly provided with nerve net, the pneumogastric ganglions and smooth muscle fibers, controverting in this the prevailing sentiment that the appendix is degenerating.

The sphincter muscle is a law unto itself. The pneumogastric muscle has no effect whatever on it. Irritation of the sympathetic nervous system causes its contraction, and the only thing that will open the sphincter is the passing down of a proper peristaltic wave.

The sympathetic nervous system inhibits the activities of the intestine with the exception of the sphincters. When irritated, out of the chromaffin bodies we have secreted epinephrin, the hormone of the sympathetic nervous system, and all activity of the intestinal tract is quieted. It becomes flaccid, its tone is diminished, and there is distention of its lumen from its gassy content. This may be for a period of rest, or it may develop a pathologic condition when long continued.

The vagus is the motor nerve of the intestine. Biologically and physiologically it is a nerve of wondrous action, connecting up the different vegetative viscera, keeping up a proper activity and tonus. In some of the lower animals it is the activating nerve to the electrical organs, and we can appreciate how the electrical discharges down through this nerve (because all nerve force is electrical) to the ganglions, which are distributed through the entire nerve net, can induce so much tone and action.

There are times when this becomes very evident, in conditions which are known as peristaltic unrest, when the bowels are moving rapidly and continuously. If they contain gas, the noises are audible. Wave follows wave. Then, perhaps suddenly all is quiet. Again, there may be times when the sympathetic nervous system closes the sphincter, the pneumogastric nerve producing a peristaltic condition almost choreic, when for hours or days there will be a tremendous churning of the intestines. Gradually it will quiet down, the sphincter will open, and there will be the usual passage on of content.

There is a wave, appreciated only by delicate instruments, which runs down the entire length of the intestine. The veins of the intestine, as they pass through the fibrous tissue into the mesentery, are provided with valves, as are the lymphatics. Every time the intestine contracts, the blood is forced into the veins and up to the liver. Mall has studied this action very carefully, and considers that the intestine is the heart or circulatory organ of the liver, and the lymphatic system of the intestinal tract. In order that there may be circu-

lation of blood and of lymph when the intestine is apparently quiescent, this wave, which comes down the entire length of the intestinal canal, acts and is a reminder of the primitive heart.

PATHOLOGIC CONDITIONS

In 1705, Hook published a work in which he suggested that it may be possible to discover the motions of the internal parts of the body by the sounds they make. Cannon, it is said, used to retire with his stethoscope on his abdomen, going to sleep listening to the sounds and studying them. Some of our writers state that auscultation of the abdomen is valueless and nothing important is heard or discovered; but I have made it a point for a number of years to auscultate every abdomen that has any enteric process. Generally, little of value is heard; but there are times when conditions are noted which are of immense importance. Conditions of peristaltic unrest are not understood except through auscultation. Simulations of intestinal obstruction can be differentiated only in this way. The atonic state of the intestine, so common in women, will give us sounds that are a clue to the condition existing.

When there seems to be a true ileus, when we have a case of "acute abdomen" in which we suspect obstruction, frequent auscultation is of much value. As soon as we hear a tinkle, then we should feel quite sure that an operation will be demanded, or if on putting the ear just above the pubes, we hear the heart sounds as distinctly as at the epigastrium, there should not be an hour's delay. It is possible that by frequent and studied observation of the sounds of the abdomen more points of importance may be discovered.

The myenteric net, being partly nerve tissue and partly neuromuscular, and being indirectly connected with the nervous system, is completely autonomic. It is a separate nervous system, controlled to a certain extent and kept within bounds of energy action by the sympathetic nervous system on the one side and by the motor nerve, the vagus, on the other. Most of the work the intestine is called on to perform is accomplished through the nerve net. Stimuli coming to it from the intestine, and chemical irritations of the mucous membrane to the terminal filaments of nerve there, may pass up to the submucous plexus and then on to the myenteric net.

The activities of this net are more pronounced and more easily induced when put on a stretch—an inheritance from its ancestors in lower life. If the intestine is exposed to the air, there follows a rapid evaporation of the carbon dioxide from the contained fluids (carbonic acid being the hormone of the nerve net, the same as epinephrin is of the sympathetic, and as cholin, a derivative of lecithin, seems to be of the vagus). Without the carbonic acid in the substance of the intestinal wall, there is inactivity of the nerve net, a parietic condition lasting indefinitely, and an inability to contract against the gases formed in the intestinal lumen, working toward the condition surgically known as ileus.

The intestine is a mesial organ. It is very long, and in its development it takes on convolutions, the large intestine passing over to the right and descending, ordinarily becoming attached to the posterior wall without a mesentery, the cecum being found at the brim of the pelvis. In this region there are perhaps more defects of development than in any other part of the body. Sometimes it is an overgrowth of cecum, allowing it

to drop deeply into the pelvis, with the production of a certain amount of drag and disturbance of the sensitive polarized area at the terminal ileum.

The intestine is held in position by embryonal bands, some passing over to the colon and giving it support, others passing up on the mesentery of the terminal end of the ileum. The cecum is generally free. The stress of the upright position may occasionally convert this normal fibrous tissue into pathologic tissue, later contracting, and in its contraction disturbing the relations of the intestine and apparently interfering with its action.

The roentgenologist in viewing the upper abdomen discovers dilated duodenums, and the surgeon also has noted the frequency of this condition. Both find a correlation between it and that which disturbs the tissues at the ileocecal region, whether bands or ptosis. Every case of ceco-appendicular deformity, so called chronic appendicitis, met in my experience, has been associated with dilated duodenum, disturbed gastric action and gastric flatulence, often associated with a type of cholecystitis, and not infrequently with a spastic condition of the descending colon.

It is curious to look back into the history of this region and see how at one time we regarded these bands and attachments as being primarily pathologic. Only a year or two before the war, Lane was removing the entire colon for what he called not an anatomic but a physiologic perversion: mutilating surgery which seems today quite unnecessary; for certainly very few colectomies now take place, and those who used to exhibit their long tubes now keep them in their darkest closet.

Before attempting to relieve a person of distressing symptoms by operative means which may be mutilating, we should try to gather in our minds with great accuracy the conditions which may be the origin of the trouble, and to know the component parts of the myenteric net and their functions, as well as their pathology.

One forceful thing was recently brought out by Crile, namely, that sturdy exercising in the open, building up the musculature of the body, making it stronger by feeding it more oxygen, had a very evident effect on the intestine. Consequently there must also be some effect on the neuromuscular tissue and the nerve net.

CONCLUSION

A few generations ago the physician occupied the whole field, both medicine and surgery; then gradually the specialties developed. As medicine grew, the result of animal experimentation and growth of other sciences, specialties grew, so that now we have an overgrowth of specialization, with a tendency to build a trench around each. In all these years we have been taught of the microcosm and the interrelation of tissues; yet in our active work we practically forget it. The time has come when we must accede to the overlapping, and in our practice as well as in our writings begin to knit the different specialties together, so that practice and study may not be warped by a biased point of view. The working out of this paper was greatly embarrassed because of the fact that the embryologist paid little attention to histology, and neither he nor the histologist to physiology. Comparative anatomy was seldom referred to, yet a knowledge of them all is necessary for a proper understanding of the architecture and function of the myenteric nerve net.

INTRATHORACIC HODGKIN'S DISEASE: ITS ROENTGEN DIAGNOSIS

HARRY WESSLER, M.D.

Adjunct Attending Physician and Associate Radiographer, Mount
Sinai Hospital

AND

CHARLES M. GREENE, M.D.

NEW YORK

The typical case of Hodgkin's disease with its enlargement of external lymph nodes is readily recognized as such clinically. The disease assumes at times, however, clinical types which may deviate from the usual form. Uncertainty of diagnosis may then arise, especially in the cases in which external lymphomas are poorly developed or absent. We have especially in mind the cases of abdominal Hodgkin's disease, or the splenomegalic form, in which the diagnosis may remain in doubt for some time unless external lymph nodes are available for section.

Fig. 1.—Mediastinal tumor type.

In view of the known frequency of involvement of the intrathoracic lymph nodes it is not unnatural to suppose that an examination of the chest might furnish some clarifying data in these doubtful or atypical cases. When we take stock, however, of the means at our disposal for the recognition of intrathoracic Hodgkin's disease, the limitations of the ordinary physical examination become apparent. Usually only the large tumor-like masses in the chest, by their size and location, are calculated to produce symptoms and physical signs, and even these may remain latent. Further, these signs and symptoms may furnish by themselves no clue to the nature of the disease, as they are common to all forms of mediastinal or pulmonary new growth. We have accordingly availed ourselves of the roentgen-ray examination in the study of twenty-five cases of Hodgkin's disease in order to determine the frequency of intrathoracic involvement and especially to ascertain whether the roentgenogram offers anything characteristic which may be of help in the diagnosis of doubtful and atypical cases.

In the first place, changes within the chest in cases of Hodgkin's disease are found with great frequency. Thus in the twenty-five cases reported, distinct evi-

dence of enlargement of the intrathoracic nodes or involvement of other lymphatic tissue was invariably found in the roentgenogram. It should be emphasized at this point that by enlargement of the bronchial nodes is to be understood, not the adenopathy normally and

Fig. 2.—Infiltrative type.

regularly found in adults, but rather an alteration in the size, shape and density of the shadows which leaves no doubt as to the existence of disease.

TYPES OF INTRATHORACIC HODGKIN'S DISEASE

The changes which we have noted on the chest plates of cases of Hodgkin's disease may be classified under four types, the significance and frequency of which will be indicated.

1. *Mediastinal Tumor.*—Thoracic Hodgkin's disease may appear on the roentgen plate typically as a mediastinal tumor. Large massive shadows are seen extend-

Fig. 3.—Isolated foci in right and left lungs; large bronchial nodes and paratracheal nodes.

ing outward from the mediastinum into the lungs; they have smooth or lobulated borders and show little or no evidence of the individual component lymph nodes (Fig. 1). Such shadows were present in eight of the cases. By themselves they offer nothing characteristic of Hodgkin's disease and cannot be distin-

guished from other mediastinal growths, such as lymphosarcoma.

2. *The Infiltrative Type.*—In this form of Hodgkin's disease the lymphomatous tissue appears to invade the neighboring lung very much as a malignant neoplasm (Fig. 2). It is doubtful whether this is a true invasion of the lung; it is not improbable that in this form of the disease there is a diffuse transformation of the intrapulmonary lymphoid tissue into granuloma. However, on the roentgen plate the borders of the apparently infiltrating mass are indistinct and irregular and appear to grow into the lung. This is an infrequent form of the disease, and it occurred in only four cases.

3. *Isolated Nodules or Metastases in the Lung.*—In a small number of cases there are seen in the pulmonary fields, and having no connection with the mediastinum, circular or oval shadows of moderate density. They are usually small, from one to several centimeters in diameter. By themselves, they are not to be distinguished from metastatic new growths in the lungs (Figs. 3 and 4).

Fig. 4.—Large right bronchial nodes; small isolated deposits in right upper lobe and in left lower lobe; large substernal thyroid.

The invariable presence, however, of lymphomatous masses at the roots of the lungs, next to be described, usually renders possible their recognition as a form of Hodgkin's disease. This type was found in four cases, always in association with one of the other forms of the disease. In accordance with the commonly accepted belief, these shadows do not represent true metastases, but are rather autochthonous foci developing in preexisting pulmonary lymphoid tissue.

4. *Discrete Nodes at the Roots of the Lungs.*—The most common form of Hodgkin's disease of the chest is the analogue of the external glandular enlargement and consists, like it, of masses of more or less discrete nodes at the roots of the lungs. It was present in seventeen cases. On the roentgenogram it provides, in typical cases, some points of distinction from other forms of adenopathy.

The shadows extend often for a considerable distance from the roots of the lungs, and individual nodes or groups of nodes retain their outline. It is characteristic of the shadows that they are faint; and in

this respect they differ from those of new growth and tuberculosis. They are particularly distinguishable from the latter by an absence of caseation and calcification. Tuberculous nodes, when they have achieved the size of those found at the hilum in Hodgkin's disease, are invariably cheesy, and the shadows are irregular and of great density. For this reason, large lobulated shadows at the roots of the lungs which are faint and homogeneous raise a strong presumption of Hodgkin's disease, a presumption which will be strengthened if there are found outlying deposits in the lungs, such as were described under Type 3. The various groups of nodes may be involved, the bronchial, bifurcation or bronchopulmonary (Figs. 4, 5, 6 and 7). Of greatest interest, however, is an involvement of the right paratracheal nodes which occurs so frequently in Hodgkin's disease as to acquire a major importance in the diagnosis. It occurred in no less than fourteen cases, either alone as a solitary manifestation of intrathoracic disease or, as was usually the case, in association with the other forms of the disease previously described (Figs. 3, 5 and 7).

Fig. 5.—Large lymphomatous mass at the root of the right lung; very large paratracheal nodes; case clinically simulated splenic anemia.

ENLARGEMENT OF PARATRACHEAL NODES

Enlargement of the paratracheal nodes is such a relatively rare phenomenon in intrathoracic disease as to warrant a slight digression at this point. Normally there is found on the right side of the trachea, just above the eparterial bronchus, a small group of lymph nodes. Owing to their deep situation, when they become enlarged they cannot be felt by palpation, nor do they produce physical signs. A moderate enlargement of these nodes, however, becomes noticeable on the roentgenogram by the production of a characteristic shadow. It is remarkable that the paratracheal nodes rarely participate in the enlargement of other groups of intrathoracic nodes. In a large number of cases of pulmonary and mediastinal new growths which have come under our observation, the paratracheal nodes were involved only once, and in this case they were only slightly increased in size. In pulmonary tuberculosis in adults in whom the bronchial nodes are usually affected, we can recall perhaps two or three cases of many thousands in which the paratracheal nodes were involved. In infants and children, on the contrary, these nodes are more often affected by the tuberculous

process, and they may then achieve a considerable size and give rise to dyspnea and stridor.

In Hodgkin's disease, these nodes appear on the plate as an oval shadow situated always to the right side of the trachea, in the upper mediastinum and below the

Fig. 6.—Large masses of nodes at both roots, on the left side extending beyond the left border of the heart; small paratracheal nodes.

sternal end of the clavicle. It varies in size from that of an almond to a hen's egg, and it is homogeneous in density.

We believe that the great frequency of involvement of these nodes in Hodgkin's disease, occurring in more than 50 per cent. of our cases, and its great rarity in other diseases with which it may be confused, may be of value in the diagnosis of obscure cases. We have in mind particularly those cases of splenic and abdominal Hodgkin's disease in which external glandular enlargement does not appear prominently in the clinical picture. A case of this type is illustrated in Figure

Fig. 7.—Large paratracheal nodes; lymphoma at the right root; small isolated foci in the right upper lobe.

5, in which the enormous spleen overshadowed the few cervical lymph nodes and simulated a splenic anemia.

The paratracheal nodes may be involved relatively early in the disease. On the other hand, they may persist after treatment when practically all other lymph nodes have receded. In a recent case, in which a small

recurrence developed at the angle of the jaw several years after apparent cure by roentgen-ray treatment, the plate showed the paratracheal nodes enlarged to the size of a walnut.

CONCLUSIONS

1. A large percentage of the cases of Hodgkin's disease have demonstrable intrathoracic lymphomas.

2. Although the roentgenogram in some cases presents nothing characteristic, in a considerable number a distinction from other forms of new growth or glandular enlargement can be made.

3. There is a frequent and unique enlargement of the right paratracheal group of nodes which occurs only rarely in other diseases.

4. In doubtful or atypical cases of Hodgkin's disease, the roentgen-ray examination of the chest may help to establish the diagnosis.

5. Roentgen-ray examination of the chest should be performed in all cases, before they are pronounced cured after treatment.

HEMOLYTIC STREPTOCOCCI IN THE NORMAL THROAT AFTER TONSILLECTOMY*

H. B. VAN DYKE, S.B.

CHICAGO

The rôle of hemolytic streptococci, especially as secondary invaders in such diseases as influenza, lobar pneumonia and measles, has been constantly emphasized in the reports of civil and military medical observers during the last two years. Hence it is a matter of importance to learn of the distribution of these organisms in normal throats under various conditions.

While most observers believe that the tonsils are often the site of growth of these organisms in normal throats, some maintain that even in normal throats the tonsils are practically always infected with hemolytic streptococci. There have recently been a number of reports of the incidence of hemolytic streptococci in normal nontonsillectomized throats as well as in throats after tonsillectomy. However, the results of many of these observations do not have much comparative value because of the failure of the investigators to include technical details in their reports. In 1906, Ruediger¹ found hemolytic streptococci in about 59 per cent. of normal throats, and Smillie² in 1917 reported very nearly the same proportion (50 per cent.). Since 1917 there have been many reports. Fox and Hamburger,³ and Levy and Alexander⁴ found that about 15 per cent. of recruits and about 83 per cent. of men who had been in service for some months were *Streptococcus hemolyticus* carriers, as shown by throat cultures. Surface smears from the tonsils and throats under various conditions have shown hemolytic streptococci to be present in normal throats in varying proportions of cases: Seventy per cent. were found positive by Irons

and Marine;⁵ 6 per cent. by Cumming, Spruit and Lynch;⁶ 28 per cent. by Nichols and Bryan;⁷ 22.5 per cent. by Opie and his co-workers;⁸ 44.5 per cent. by Blanton, Burhams and Hunter;⁹ 47 per cent. by Simmons and Taylor;¹⁰ 58 per cent. by Pilot and Davis;¹¹ and 57 per cent. by Tongs.¹² Blake¹³ reports that in the absence of streptococcus epidemics less than 10 per cent. of normal men in army camps harbor hemolytic streptococci in their throats, but that this proportion is increased by from 300 to 400 per cent. during streptococcus epidemics. It has also been shown that only cultures of the crypts of excised tonsils may reveal the organisms. Nichols and Bryan⁷ obtained positive crypt cultures in 75 per cent. of excised tonsils. Pilot and Davis¹¹ found that while hemolytic streptococci could be detected by surface swabbings of the tonsils in 61 per cent. of their cases, crypt cultures of the same hyperplastic tonsils after excision showed 97 per cent. to be infected by the organism. Similarly Tongs¹² pointed out that surface cultures of unexcised tonsils showed hemolytic streptococci in 60 per cent. of the cases, and that crypt cultures showed the organism in 83 per cent. of the same tonsils. Hence it is probable that in normal tonsils and throats hemolytic streptococci occur in even higher proportions than have been indicated.

The proportion of hemolytic streptococci in normal throats after tonsillectomy has been reported as being 13 per cent. by Nichols and Bryan;⁷ 23 per cent. by Simmons and Taylor;¹⁰ 15 per cent. by Pilot and Davis;¹¹ and 5 per cent. by Tongs.¹² All investigators who have examined throats after tonsillectomy agree that such throats harbor far fewer hemolytic streptococci than nontonsillectomized throats. I wish to report some observations on the incidence of hemolytic streptococci in the throats of tonsillectomized individuals in good health (Table 1).

TECHNIC

All throat cultures were thus made: A sterile cotton swab was gently but thoroughly rubbed against the walls of the tonsillar spaces, over the pharyngopalatine arch and the posterior wall of the pharynx, and at once used to inoculate an enrichment broth. This consisted of from 5 to 6 c.c. of plain broth (made with 15 gm. of Fairchild's sugar-free culture peptone, 5 gm. sodium chlorid, and distilled water sufficient to make 1,000 c.c.), to which had been added from 6 to 8 drops of defibrinated goat's blood. The organisms were cultivated for twenty-four hours in the enrichment broth, after which surface smears were made on 1.7 per cent. agar containing about 10 per cent. of defibrinated goat's blood, and shake cultures were prepared by

inoculating and plating at 45 C. tubes of blood agar of similar composition. Like Tongs,¹² I found a somewhat larger proportion of hemolytic streptococci by the shake method than by the surface smear method. The plates were cultivated and observed for forty-eight hours. Organisms from hemolytic colonies when present were inoculated into plain broth, made as described, and after twenty-four hours' cultivation were again plated in blood agar by the shake method to observe the purity and hemolytic action of the strain. At the same time the staining

reactions and morphology of the broth cultures were studied. From the same broth cultures, blood agar slants of 1.7 per cent. agar containing about 5 per cent. of defibrinated goat's blood were inoculated and kept at a temperature of 37 C. for twenty-four hours, after which they were sealed with paraffin and corks and placed in an ice-box for later use in fermentation tests.

The hemolytic streptococci found were gram-positive organisms which in broth formed chains of from five to sixty cocci, each strain forming chains of approximately the same length. Definite differences in the size of the individual cocci were common. On blood agar were noticed chiefly two types of colonies: one

markedly hemolytic, the individual colonies being surrounded after twenty-four hours by a hemolytic zone from 2 to 4 mm. wide, and another considerably less hemolytic, its surrounding hemolytic zone being less clear and usually only about 1 mm. wide. Microscopic examination of these colonies under low power revealed the fact that, while all of the corpuscles in the hemolytic zone of the first type of colonies were completely hemolyzed, hemolysis was not quite complete in the hemolytic zone of colonies of the second type, and at the same time the corpuscles which were not hemolyzed were little discolored. The first type of colony resembled that described by Brown¹⁴ as the colony of the Beta (β) type of hemolytic streptococcus, the second resembled Brown's¹⁴ Alpha prime (α') type of hemolytic streptococcus. The organisms are so designated. After cultivation in the enrichment medium almost always there was a great preponderance of either the Alpha prime or the Beta type of organism when either was present.

FERMENTATION TESTS

In the performance of the fermentation tests, one loopful of a twenty-four hour broth culture of hemolytic streptococci from preserved blood agar slants was transferred to from 1 to 2 c.c. of the carbohydrate broth (plain broth as described, to which was added, each to the amount of 1 per cent., 5 per cent. litmus solution and carbohydrate). No raffinose was available. Observations were made over a period of eight days, although the fermentation reaction was practically always plain after three days. Twenty-one strains were tested by the fermentation reactions, and the results are illustrated in Table 2.

COMMENT AND CONCLUSIONS

In the series of tonsillectomized throats of individuals in good health it was found that in nine, or 16.4 per cent., there were markedly hemolytic streptococci. In sixteen, or 29 per cent., of the throats were the less markedly hemolytic streptococci resembling Brown's¹⁴ Alpha prime type. Thirty, or about 55 per cent., of the throats examined revealed no hemolytic streptococci. There seemed to be no significance in the time elapsing between the removal of the tonsils and the bacteriologic examination of the throat for hemolytic streptococci. In several of the cases the Beta type of hemolytic streptococcus was present in the absence of clinically visible changes in the throats. The fermentation reactions of these streptococci were typical of hemolytic streptococci. According to the classification of hemolytic streptococci by fermentation reactions as suggested by Holman,¹⁵ the organisms tested would be divided into two groups, *Streptococcus anginosus* (fermenting lactose but not mannite and salicin) and *Streptococcus pyogenes* (fermenting lactose and salicin but not mannite).

The method employed in this work differs from that of most investigators in that a routine preliminary cultivation of the throat cultures in blood broth was made. While some reports mention streptococci whose

hemolytic action is incomplete (Alpha prime type), none give very definite data on the proportion of such organisms. The Beta type of hemolytic streptococcus is probably the type referred to by most authors as hemolytic. Hence my findings, namely, that 16.4 per cent. of the tonsillectomized throats harbored markedly hemolytic streptococci, while higher than those of Tongs¹² and lower than those of Simmons and Taylor,¹⁰ agree quite closely with the observations of Nichols and Bryan,⁷ and Pilot and Davis.¹¹

THE REHABILITATION OF A MEDICAL RESERVE FOR THE ARMY*

SANFORD H. WADHAMS, M.D.

Colonel, M. C., U. S. Army

AND

ARNOLD D. TUTTLE, M.D.

Colonel, M. C., U. S. Army

WASHINGTON, D. C.

The United States Army is now facing what may appropriately be characterized as a period of critical transition. Demobilization of the vast war machine built up during the past two years has been more or less successfully accomplished.

The permanent personnel of the regular establishment would welcome a speedy return to a peace time basis and the development of a military organization capable of functioning efficiently. In one of the hearings before Congress, not long ago, some one tritely remarked that nearly every permanent officer these days is carrying about in his pocket an army reorganization bill—the figment of his own fertile imagination. It is to be hoped and confidently can be predicted that the Congress, by avoiding the “extremists,” will hit on a happy medium and enact a law that will permit the army to develop along the lines which the experience gained in the world war has demonstrated will best meet the needs of our national ideals. What is most earnestly to be hoped for is a law which will provide the framework of a real military policy—that will-o'-the-wisp which has always eluded us. Even an imperfect plan is better than none at all. Nations, like individuals, require a goal at which to aim. As a nation we have for a moment had a vision which has fired us to supreme effort. Are we going to lapse back into the old habit of drifting with the current, or are we going to remember the thousands of young men we have left behind in France and turn our thoughts to a constructive program which, if it does not keep us out of wars in the future, will at least prevent the needless sacrifice inseparable from our chronic state of unpreparedness?

Diligent efforts are being made by our national legislators to get at the meat of the nut and formulate a basic military law embodying as many as possible of the good features developed by our experience in the world war, and eliminating, or at least trying to eliminate, such defects as have been demonstrated.

“In time of peace prepare for war” still holds good. We fervently hope that the present generation has seen

the last of war on a big scale. Nevertheless, we are not prepared to admit that the millenium has arrived or that an army's usefulness, in spite of its *raison d'être*, terminates with a war, although a study of our military history would indicate that that belief is very generally held. An individual applying the same reasoning would discontinue all life insurance on recovery from a dangerous illness on the theory that all risk of death had passed. From out the welter of the past few years the one fact which must have been impressed on the mind of every American is the utter folly of ignoring the basic principles of national preparedness and national defense, and calmly awaiting a declaration of war before attempting even to assemble, train, equip and properly classify and distribute the enormous number of men called to the colors. Such a policy pursued long enough will certainly result in our undoing. We cannot always hope to find some other nation willing to step into the breach and hold off the foe for years while we fumble and grope, legislate and investigate, waste human lives because we have no clothing or blankets, and spend billions of dollars without visible result in a belated and frenzied rush to prepare. Constructive legislation is rendered increasingly difficult after each war. War loans place a heavy burden of taxation on the citizen, and therefore public expenditures must be curtailed. For many years before the late war, army appropriations were rather less than 10 per cent. of the interest now being paid on our war debt. Tax payers grumble but accept the situation philosophically, never pausing to analyze the matter sufficiently to see that a more generous and broad-minded treatment of the question of national defense in the past would in all probability have obviated the necessity of raising billions on billions of money to prosecute the war just ended.

Today all branches of the military service are confronted with important and pressing problems, on the wise solution of which our national safety in the future may rest. It is proposed in this paper to present two of these problems which, while of moment to the whole military establishment, are vital to the Medical Department.

FIRST PROBLEM: ESTABLISHMENT OF ADEQUATE REGULAR MEDICAL CORPS

The Regular Medical Corps must be recruited up to its full authorized strength. More than 700 vacancies now exist. Under present conditions of pay and promotion, an Army commission seems destined to go begging. Compared with the rewards now enjoyed by his brother practitioner in civil life, the career of his military prototype is one of relative renunciation. It is freely granted that service conditions must be made much more attractive for the embryo military officer. As a result of legislation probably to be enacted during the present session of Congress, in the matter of increase in pay and allowances and speedier promotion (Captain after three years' service), it is believed that we may soon be able to hold out to prospective candidates sufficient inducement for them to join the regular corps. An additional incentive, the details for the practical application of which are now being studied and developed in the Surgeon-General's Office, and which was recently commented on editorially in *THE JOURNAL*,¹ will be a provision whereby properly qualified men in Class A medical schools, on

* Note, Jan. 16, 1920.—Time mellow all things. Since completion of this article, sentiment among the Medical Reserve seems to have undergone a very decided change for the better, if the number of applications for commission now pouring into the War Department can be accepted as a criterion. At this date a total of 8,000 Medical Reserve officers have already been enrolled, and in addition there are about 4,000 applications on hand awaiting action.—The Authors.

1. Securing Officers for the Army Medical Corps, editorial, J. A. M. A. 73: 1845 (Dec. 13) 1919.

the termination of their fourth year of study, can be offered internships, carrying pay, in our larger military hospitals—this with a view to affording them opportunity, while finishing their hospital year, of gaining an insight into the different phases of military life and thus making the appointment a stepping stone to a commission in the regular corps. Furthermore, the day may not be as remote as one might at first think when we shall have to resort to some form of governmental subsidy for the education of such medical students as may elect military careers on the termination of their classical courses, and decide to qualify as medical officers of the army under the financial assistance provided for them by the government. With the Medical Corps of the permanent establishment up to its full authorized quota, our peace time obligations can be met.

SECOND PROBLEM: ESTABLISHMENT OF AN ADEQUATE MEDICAL RESERVE

The second and more important problem has been made the title of this paper. The number of names on the present roster of the Medical Reserve Corps is far from satisfactory. From our experience in the recent war, it is obvious that it must be built up in time of peace to a point far beyond that ever achieved by us in the past.

What are the prospects? Under present conditions we are constrained to confess that they are not very bright. Let us briefly review some of the causes which lead us to entertain such a pessimistic conclusion.

During the war there were enrolled in the army approximately 30,000 medical officers from civil life. Prior to his discharge, each officer was requested to signify his desire with regard to accepting a commission in the Medical Section of the Officers' Reserve Corps on the inactive list. Excluding some 1,500 officers still in temporary service, the latest figures at hand reveal that only 5,000 medical officers from civil life who saw active service during war at home or abroad have so far elected further affiliation with our army reserve. Of this number, when appointments were eventually sent out, about one third declined and returned the commissions offered them. To be exact—to date (Dec. 1, 1919) 3,787 acceptances and 1,261 declinations have been received.²

In one representative list of declinations taken at random from the files of the Surgeon-General's Office and containing 327 names, the commissions sent out but declined were: two in the grade of lieutenant-colonel, fifty-five major, 181 captain, and eighty-nine first lieutenant. (In this connection it is of interest to note that approximately one sixth of these commissions offered but declined were in field grades.) From the foregoing, it will be seen that thousands of experienced medical officers have been discharged and returned to their practices in civil life, leaving behind them in the minds of their former military associates no question of doubt as to the keenness of their desire for an absolute divorce from the military service. Many have left us with nothing but an expression of the bitterness in their hearts. Dissatisfaction over their lot while serving with the colors is common.

In justice to them it should be said that while combat activities were on, they served bravely and patiently even while smarting under what appeared to be injustice and lack of appreciation. With their duty to the country fulfilled in fullest measure of devotion, a wave

of revulsion swept over many of those about to be discharged. Immediately following the armistice, universal discontent and dissatisfaction became rampant among the reservists. Some spared no pains to voice their indignation and disgust at the lot which fell to them during the war and the situation in which they found themselves when the armistice anticlimax overwhelmed them. Disappointed, their sole aim was to get out of the army as quickly as possible and forget it.

In the matter of securing initial commission and subsequent promotion, "political influence," "wire pulling" and "peanut politics" were openly charged. As one man put it, "Why shouldn't a man become disgusted when he was made to realize that 'pull and bull' won out over patriotism and efficiency in the matter of securing commissions and promotion."

While in some respects the foregoing typical statements are somewhat far fetched, the basic causes of the discontent now pervading the ranks of our ex-reservists are clearly understood and deeply deplored by those in the regular service. There is a psychologic and pecuniary foundation that requires no further discussion here. The fact remains that a commission in the Medical Section of the Officers' Reserve Corps at this time seems to be unattractive to the majority of physicians in civil practice.

Even among those who do not harbor any ill feeling over their treatment in the army during the war—and they, we feel confident, constitute the majority—a statement frequently heard is that commissioned status on the reserve list as now provided for carries with it no special prestige or advantage, but on the contrary, certain restrictions or obligations that the average medical man in civil life prefers not to assume. Furthermore, he will tell you it was amply demonstrated in the recent war that when the country needed medical officers they promptly responded, no matter what the personal sacrifice may have been, and that they all continue to remain sufficiently loyal and patriotic to respond in the future to any call of the nation for aid in time of actual hostilities. At any rate, he is "fed up" on the army and turns a deaf ear toward any proposition which would necessitate any further interest in it.

Many of them cite or dwell at length on the fact that the older officers—in point of service—of the Reserve Corps who joined the colors at the beginning of the war found themselves after several years of faithful and efficient service returning to their homes junior in rank to medical officers who had not joined the reserve in time of peace and did not do so until the war was well along. In fact, the recriminations now being directed at this phase of the civilian medical practitioners' military service have a very considerable basis in fact and constitute the crux of the whole question. How this situation arose will not be discussed here. It is well, perhaps, to point out that the administrative difficulties of hastily expanding a corps of about 400 officers to one of 30,000 under the confusion of rapid preparation for war are very great.

When it is borne in mind that the public is apathetic in time of peace toward any measure of military preparation, and that it had been impossible to secure legislation outlining a military policy to meet such an emergency, it is not surprising that mistakes and injustices occurred. They always have occurred and they always will occur until such time as a definite plan for the mobilization of the nation can be worked out

2. See Footnote, p. 450.

and put into effect before the emergency is on us. It is illuminating and extremely significant to observe that the reserve officer places this item of relative rank high up among the desiderata meriting consideration, and accords to it practically as much importance as does the regular army man. This is a psychologic factor which must be given due weight in attempting to devise a corrective for the condition now existing.

For purpose of illustration let us assume that in time of emergency two practitioners in the same community volunteer their services. Both receive commissions as first lieutenants and both perform equally meritorious service. When their services are no longer required, both return to their homes to resume practice; one, however, is now a lieutenant-colonel, while the other is still a first lieutenant. If it happens that the latter is the older and had become a member of the Reserve Corps before the war, attended camps of instruction, etc., his feelings can be better imagined than described. Obviously there must be something radically wrong with any system which can permit such injustice to occur.

A just promotion policy had not been formulated in time of peace. Moreover, such a policy could not have been worked out for the reason that we had no basic military policy on which our war effort was to be built. Such a policy can be elaborated and enacted into law only by the government, and this each succeeding administration has failed to do. It is one of the saddest commentaries on this lack of a policy providing for preparation in time of peace that so many of those splendid medical men serving at the front with combat troops during the war receive little or no recognition in the way of promotion for hard and dangerous duty well done. Many of them rendered brilliant service throughout all the battles participated in by the American Expeditionary Forces and found themselves still in their original grades when the war ended. Others, firm in the belief of the holiness of the cause, made the great sacrifice. Undying glory and honor have been brought to the medical profession. While it was a great privilege to have been permitted to serve, we shall have failed in our simple duty if we do not attempt to profit by the lessons of the war.

Not once but hundreds of time have we been told by medical officers that this subject of relative rank in the home community carries great weight with them.

It is a safe assumption that the Medical Officers' Reserve Corps as now constituted and conducted does not offer any alluring inducements to the thousands of experienced men who are returning to civil life with valuable military experience. We can ill afford to lose their sympathetic cooperation, their interest, and the knowledge they acquired in following the devious ups and downs of a military career during the past two years. And in this connection it cannot be too strongly emphasized that the Medical Corps of the Army can achieve progress in the cause of medical preparedness only as it works in cooperation with the civil medical profession of the country. The war has shown us that the problems of the former are likewise the problems of the latter. The time has passed when any country can hire men to fight its battles, and other men to salvage the human wastage of war. It is well that both the medical officer of the army and his civilian brother should meditate on this aspect of the nation in arms.

If we adhere to generalities and assume that inequality of promotion and consequent disturbance in

relative rank had more than anything else to do with bringing about the existing disaffection, where lies the remedy? How can the Reserve Corps be made an instrument for preparing the civil practitioner to assume his military obligations with efficiency and justice to himself? Radical changes are necessary. As to that, the civil medical profession and the medical officer of the army are well aware. It remains, therefore, to determine on a remedy.

PROPOSED REORGANIZATION OF THE RESERVE

The Medical Corps of the Army sponsored the inauguration of the Reserve Corps idea in this country at the time when General Robert Maitland O'Reilly was Surgeon-General of the Army. Its pioneer work in having the bill of 1908 enacted was later emulated by other branches of the military and naval services. Existing legislation governing the Reserve Corps, while sound in principle, is far from satisfactory and needs amendment in a constructive fashion. Therefore, if we are again to have a happy, contented, well-balanced and proficient reserve, cooperating and working in close harmony with its parent organization, the Medical Corps of the Army must again step out and propose the establishment of a reserve system which will embody the results of experience under the original reserve act prior to and during the war, retaining its good features and eliminating its defects. Among the latter we are disposed to accord lack of provision for promotion first place.

Our proposition calls for the assistance and cooperation of the general staff at the War Department, since many of the features desired could be put into effect by that body without further recourse to Congress; but where the latter course is necessary, the enactment of such simple legislation as will permit us to arrange the list of Reserve Corps officers just as is done with officers of the Regular Corps. How can this be accomplished?

FIRST STEP: A LINEAL ROSTER FOR RESERVE OFFICERS

Place all medical reserve officers on one lineal list and thereby establish (among themselves) relative rank, just as is done in the case of officers in the regular establishment. All officers are to be commissioned in grades from colonel down to and including first lieutenant and arranged on the list in order of their rank and subsequently promoted according to seniority. The proportion between the various grades should be the same as now authorized for the Regular Medical Corps. (Present legal allowances in Medical Corps are: colonels, 3.16 per cent.; lieutenant-colonels, 5.42 per cent.; majors, 23.7 per cent.; captains and lieutenants, 67.72 per cent.)

After readjustment in rank of those now in the reserve, and of such former members of the reserve as may rejoin under this new scheme has been made as described below, all original appointments to the reserve, in peace or war, and irrespective of the age or professional standing of the applicant, shall be made only in the junior grade—that of first lieutenant—the new appointee to take his place on the lineal list at the foot of that grade. This provision would place a premium on early enrolment in the reserve and a penalty on temporizing or great delay. Once commissioned in the reserve, a young medical man's relative position on the list is established and he will always have precedence on the *peace time list* over

those subsequently joining. Let the recruit begin at the bottom while he is young, preferably just out of medical school.

However, some exceptions to this rule would have to be provided for. Any officer of the Regular Medical Corps or of the National Guard who resigns his commission or is discharged under honorable conditions should be admitted to the reserve list in the grade and with the corresponding lineal rank he held in those forces when discharged. Such increments should be carried as extra files until they can be absorbed in the annual readjustment.

In this connection it should be remembered that a medical man cannot hold two commissions. If he is a member of the reserve he must resign in order to accept a commission in the National Guard. By doing so he will create a vacancy in the reserve, to be filled by the promotion of those below him on the lineal list. If he subsequently resigns from the National Guard and desires to resume a reserve status, he should be recommissioned in the reserve in the grade and take his place on the list in the same position he would have occupied had he not left it.

HOW TO INAUGURATE THE ROSTER

1. At any time within one year after the passage of the proposed act, admit to this newly created Medical Section of the Officers' Reserve Corps, on their own application and in the highest grade occupied by them, all medical officers who served during the world war and are eligible for reserve commissions.

2. Equitably distribute the number of various grades as legally authorized, computed on the total number of officers enrolled in the Reserve Corps.

3. Redistribute grades for purposes of promotion annually, based on the total strength of the reserve at the end of each calendar year.

In the initial adjustment, it shall be provided, however, that the minimum number of field grades authorized shall not fall below the reserve on a million men, i. e., 7,000 medical officers. This proviso would permit us to start off with a reserve list of at least 221 colonels, 379 lieutenant-colonels, 1,659 majors, and the balance in captains and lieutenants. For a reserve enrollment of 14,000 medical officers, our allowance would be 442 colonels, 758 lieutenant-colonels, and so on.

With the foregoing minimum allowance in field grades, every reservist could be assured of receiving a commission in the highest grade held by him during the war; and on recommendation of the Surgeon-General, many of those not suitably rewarded by promotion during the war could now be promoted. In fact, it would assure nearly every junior officer an extra grade. As additions to the reserve were made and the list grew, there would, of course, occur a corresponding increase in the higher grades, thus creating an opportunity for further promotion.

In the annual redistribution, should there be found in any year an excess of officers in the field grades, no demotions would be made, but further promotions to those grades would be suspended until the extra files had been absorbed either by eliminations in the grades showing the surplus or by additions at the bottom of the list, or by a combination of the two. In accomplishing the initial adjustment, the relative rank in each grade should be arranged, by recommission if necessary, and preferably in the order of age of the individual, with the result that older men would be

placed above the younger in each grade. While this is not essential, it is highly desirable and is a good principle to follow for the reason that it would stimulate a constant flow of promotion for those officers below them on the various lists; whereas with younger men at the top, considerable blocking of promotion will result. In other words, a young man remains on the list longer than an older man, with the result that the latter passes off it without enjoying a vacancy in the grade occupied by the former. It is believed that this primary readjustment could be equitably and fairly brought about in a methodical manner to the satisfaction of all concerned. Of course, some compromise would be necessary. Only one man could be No. 1 in each grade. Some man would have to be content with remaining for the time being No. 221 on the list of colonels, and another one No. 379 on the list of lieutenant-colonels and so on down—to use an army phrase—to the “goat” lieutenant, the last man who joined the reserve.

SECOND STEP: SUBSEQUENT OPERATION OF THE ROSTER

Now let us assume that what we might term the war-time or readjustment phase in the evolution of the new Reserve Corps has been accomplished as described above. Under the proposed scheme there may have been enrolled, let us say, 20,000 of our ex-war reservists. But to take a concrete example, assume only that the 7,000 officers noted above constitute the Medical Reserve Corps when the list is first established and printed. In other words, we would have 221 colonels, 379 lieutenant-colonels, 1,659 majors, and 4,741 captains and lieutenants (any increase above the 7,000 taken as an example would result in a proportionate increase in the various grades just given). After the lapse of one year, no further initial appointments in the higher grades would be made. From that time on, all appointments would be made in the lowest grade, or that of first lieutenant, and the applicant so appointed would, according to the date of his commission, take rank on the lineal list at the foot of first lieutenants. Promotion thereafter would be made just as in the regular corps, by seniority as vacancies occur. These vacancies in the various grades would be created, for example, by death, by discharge for cause, by resignation, or when the reservist reaches the age of 64 years. This is the retiring age for regular officers, and is favored over the 59 maximum now prescribed for reserve officers. The period of one year suggested above is not arbitrary, but it is evident that a time limit must be fixed before the expiration of which all ex-medical officers must have decided whether or not they wish to hold a commission in the Reserve Corps. This period would be the time required for bringing before the medical profession of the country the approved plan for the reorganization of the Reserve Corps.

Removal of a colonel from the list through the operation of any of the reasons given above would immediately result in the promotion of the senior lieutenant-colonel, the senior major, and the senior captain. Promotion to captain would be made after three years' service, and would not depend on vacancies. One point that we particularly desire to make clear here is that through the operation of such a list as proposed by us an officer on the reserve list is in line for promotion, and would be promoted as vacancies occur, irrespective of the fact that perhaps he had never served

a single day on active duty. Under this scheme, every man takes his place on the list and is considered eligible for promotion exactly as is every other officer on that list. No limitations should be placed on eligibility for service in grades. Appointed as first lieutenant, we see no reason why an officer should not after the lapse of twenty or more years, provided he has made a faithful effort to keep up with the progress of medico-military science, be fully capable of performing the duties of a colonel, in which grade he would probably find himself at that time if this plan is accepted. The point that we particularly desire to make clear is that under this

the records of 10,596 officers, is 1½ inches thick. For desk and ready reference purposes, this is a handy and convenient size.

With the Medical Reserve Corps organized and conducted on a lineal list basis as proposed above, the publication annually of a separate Medical Reserve section of this official Army Register is essential. In other words, we would have issued annually the present official Army Register, one volume of which would contain the names and records of "Officers of the Regular Establishment," and one or more volumes to contain the names of officers of the Medical Reserve (no volume should exceed 10,000 names). While true that the medical officers in the National Guard are prohibited from holding a commission in the Medical Section of the Officers' Reserve Corps, they nevertheless form part of our national reserve. There would be no objection to the publication of a separate register for these officers; but as their strength, based on past records, would probably never exceed an aggregate of 1,000 medical officers (the maximum number in 1916 was only 800 officers) there is no reason why their names, rank, National Guard assignments, military record, etc., should not be incorporated in the volume, immediately following the names of officers of the medical section, Officers' Reserve Corps. In this event the proper title for the register should read:

"OFFICIAL ARMY REGISTER"
(RESERVE MEDICAL OFFICERS)

instead of:

"OFFICIAL ARMY REGISTER"
(MEDICAL SECTION—OFFICERS' RESERVE CORPS)

We see no reason why each section of the Officers' Reserve Corps should not also publish a register. For example, we would propose that there be one register also for reserve infantry officers, another register for reserve quartermaster officers, and so on to cover all of the reserve officers enrolled by the army.

We would pattern the preparation of this register of reserve officers very much after that now being used for officers of the regular establishment. To make the register generally useful we would, however, embody certain changes therein. For example, we would arrange all officers under their different grades with their relative rank in each grade indicated by serial numbers. The first page of the register would start with the colonels and be headed by the name of the officer who was number one on the list of colonels. Colonels, of course, would be followed by a list of lieutenant-colonels and so on down to the junior lieutenants.

As for the regular register, the record would show for each officer, in the first column the name, rank, date of rank, military awards, and college and university degrees with date of these. In the second column could be shown the military service, such as dates of the various commissions, etc.

In the third column could be shown the home address, specialties or nature of practice in which engaged, hospital appointments, officerships in societies, etc. In the fourth column, place and date of birth and in the fifth, state from which appointed (the foregoing all to be shown in the first section of the register).

In another section of the same register could be shown a table of the distribution by states, this to be followed by casualties, showing by name, resignations, deaths and discharges during the year. This could be followed by insertion of histories of organizations and

1918.

A page (reduced) from the official Army Register, 1918.

scheme a reservist may never see any active service—except such attendance at camps of instruction as he may elect—yet a steady flow of promotion is assured.

THIRD STEP: PUBLICATION OF A SEPARATE MEDICAL RESERVE SECTION OF THE OFFICIAL ARMY REGISTER

The War Department now publishes annually a compilation known as the Official Army Register. This contains the names, records, etc., of all officers of the regular army. During the war its publication was suspended, the last prewar register being issued in December, 1915. The publication of this register was resumed for the year 1918.

For those readers who have never seen an issue of this document, we might add that it is a paper covered book 9 by 6 inches and for the 1918 issue, containing

such other items of historical data as would prove of general or official interest. This might well include a brief history of the organizations and operations of all the sanitary organizations utilized during the world war but which have now gone out of existence.

Schedules of pay tables of the army should follow this, and lastly the general alphabetical index of all the names contained in the register. Basic laws affecting the reserve corps should be inserted in fly leaf.

This register would prove a very useful document. It would make an excellent reference record, something that we now sadly lack. During the war, regular officers in charge of large projects knew absolutely nothing of the make-up of the Medical Reserve Corps. The possession of a copy of this register would have proved invaluable to them in making selections and assignments. Every officer in the reserve should be furnished a copy of this register annually. In that way he would become acquainted with the names, relative rank and location of other reserve officers, particularly those in his own or nearby communities. It could also be placed on sale at the Government Printing Office at cost price, and made available for libraries, medical societies, etc., which would be interested in having copies for reference.

Reference to the register would definitely fix the lineal rank of every officer whose name is borne thereon just as is now possible for officers of the regular establishment. Another thing, as the years went on it would be a complete record of a man's service from the time he joined, when his name was away down on the list of lieutenants, to the present when perhaps he might be well up on the list of colonels. "Know ye one another!" So much for the book.

FOURTH STEP: TRAINING OF RESERVE OFFICERS

The training of reserve officers will be discussed in brief and only because it has some relationship to our scheme and will require careful consideration if it is adopted. If a young man joins the reserve today as a first lieutenant, and as the years go by is successively promoted through the grades of captain, major, etc., until twenty-five years hence, let us say, he is a colonel on the list, and may have attained that rank without ever having had a single day of active duty—should we remain content to let the matter rest there? Most emphatically, No! We believe that no reservist would accept promotion to a higher grade without at least making a faithful effort to keep abreast of the medicomilitary requirements of the grade in which he would have to serve were he suddenly ordered out in time of war to join the colors. In fact it will be necessary to require of all reservists some attention to training or instruction, and eliminate those who fail to attach any great importance to that end of their military status. It is safe to assume that any fair minded and conscientious reservist would demand instruction in the event that the war department did not provide and require it. But in imparting this instruction by no means should reversion to the old order of things be permitted. However, the entire subject of training of our forces has not yet been developed, and any ideas that we might advance now would be premature until we become familiar with the basic fabric on which our reorganization is to be built. In a general way, however, we might add that the Medical Department desires to maintain two schools, one at Washington which will be known as the Medical Department Technical School and in which will be taught strictly professional work,

and another one to be established at some camp not yet selected and to be known as the Medical Department Field Service School, where instruction in all field matters will be given. In addition to these two schools, Medical Department personnel will also have the option of access to training camps, particularly those in which combined maneuvers are held.

At the Medical Department Field Service School we hope to maintain complete exhibits of all Medical Department units, sanitary devices, etc., with sufficient trained personnel always on hand to demonstrate their uses. For example, among many other exhibits one should be able to see there a sanitary train in operation, an evacuation hospital complete and ready to function, and at times a standard hospital train. When our educational program has been placed on a firm foundation, we should permit all reservists largely to follow their own inclination and elect the time, place and character of the course which they desire to take. With a large reserve list, all the men on it, by means of suitable questionnaires sent out at stated intervals, will be encouraged to elect the kind of work they desire to follow if called into active service. Some would elect administrative work, others mobile base or evacuation hospital instruction, and still others duty with combatant organizations.

A complete pamphlet on all Medical Department training resources should then be compiled and distributed among reserve officers. We should make these instruction centers so attractive and a residence therein so interesting that the reservist, instead of spending all of his vacation in the mountains or at the seashore, would take a part at least at one of these centers. They should be open for attendance by these officers the year round, barring, of course, climatic conditions where necessary. Then say to the reservist: "The door is open, come as often and stay as long as you like." To meet the expense item, there should be written into any basic training law a provision that any reserve officer proceeding from his home by the most direct route to the training center he elects is automatically (under his commission) placed on active duty and entitled to the legal traveling expenses, pay, etc., during the time that he is proceeding to, remains at, and is returning from the training center; the authority for such pay and allowance while under instruction not to exceed that for one month in any calendar year, but to be cumulative up to four years. This clause would enable the reservist, if he so desired, to attend the instruction center for four months on full pay once every four years or for two months every two years, in the event that he did not care to spend his annual monthly vacation in this manner.

Herein we are attempting only in a general way to state how we believe training, particularly for reserve medical officers, should be developed and encouraged. Any plan adopted would necessitate the incorporation of many details that need not be recited here. For example, at some of the centers there would necessarily have to be some check made on the attendance. A man would probably be required to write direct to the center beforehand and receive permission to come at a certain time, in order that he might be assured of accommodations.

Furthermore, we would reduce didactic instruction to an absolute minimum. Instruction should be by demonstration and actual working exhibition of the specialty in which the reservist is interested. Going through squads right, squads left, right hand salute,

left hand salute, and lining up with mess kits should be relegated to the background. Of course the reservist recruit, the man just out of college, who knows nothing of soldiering would need some instruction along these lines. In fact, he would probably be the first to suggest it. Nevertheless, we want to emphasize the fact that this feature of his instruction should be carried on only long enough to give him an insight into military requirements and to help him to adapt himself to military customs. With it, he can save himself needless embarrassment when called to the colors; without it, he would only be adding to his troubles in such a contingency.

Another point to be emphasized is avoidance of taking up too much of the student officers' time with paper work. For those men particularly interested in it, every opportunity should be extended to familiarize them with this subject; but for the average reservist we would urge very little of this work. If successful in developing our proposed Medical Service Corps, we should always in the future have an ample number of trained officers to carry on this work in hospitals and other sanitary formations and free medical officers from the necessity of devoting their time to this phase of what has heretofore been an irksome task.

FIFTH STEP: PROMOTION IN TIME OF WAR

As predicted above, for a long time to come at least we shall hope that this question will not cause us any great concern. Let us put our house in order by establishing our peace-time list on a methodical and equitable basis. The matter is briefly treated in a subsequent paragraph; but here it is desired to emphasize the urgent necessity of devising some system of promotion in time of war to protect the interests and reward the reservists who have had years of service on the peace-time list.

The adoption of our peace-time list would form a foundation for and greatly facilitate the equitable distribution of promotion in war. It is safe to assume, however, that selective promotion will always prevail in time of war. Also at this time if the excellent principle followed in the recent war is adhered to, the medical officers of the Regular Corps, Reserve Corps, and National Guard become part of the combined or greater U. S. Army. The minute they enter on active service, all National Guard and reserve officers are recognized as being on the same footing as the regular officers, and lose their reserve and National Guard identities.

All new appointments to a war army should be made only in the lowest grade—that of first lieutenant. All promotions into the higher grades of the combined army should be made from one of three lists mentioned—i. e., the former regular list, the former reserve list, and the former National Guard list. For purposes of equalizing promotion as far as possible we would have all men who are promoted to a higher grade in the U. S. Army during war time automatically create vacancies in the other lists when they leave them. "On paper" only this would result in double promotions and enable seniors on the list who are not in a position to render service that attracts attention and results in selective promotion to enjoy at least some promotion as a result of their relative position on their own lineal list. It is only natural in war time that promotion shall go to the man on the ground. To that extent there is a considerable element of chance. The man who is immediately available and who has demon-

strated his fitness for a larger task will naturally be selected, even though another man of equal or greater ability is known but not immediately available.

On the declaration of war, no further appointments to the Medical Reserve Corps or National Guard would be made. All commissions would be made in the U. S. Army. All officers on the regular, reserve or National Guard lists retain the permanent rank held during peace time on those lists, but automatically become members of the "Medical Corps, U. S. Army," the great war time pool which recognizes no distinction such as regular or reserve. All new appointments to the U. S. Army during war are to be made in the grade of first lieutenant, all selective promotions to be temporary and made in that army. Assuming that all men on the regular, reserve or National Guard lists are proficient, they should enjoy a normal flow of promotion during war time even though they may not be singled out for selective promotion. To effect this and remedy a fault recognized during the last war, every time a man is promoted to the combined war list let it be assumed for purpose of computation only that he has temporarily created a vacancy in his old lineal list and that it results in the promotion of the seniors in each grade on that list below him. In other words, this scheme would result in "double" promotion.

SIXTH STEP: REVISION OF TABLES OF ORGANIZATION AS THEY AFFECT MEDICAL DEPARTMENT DISTRIBUTION

This does not require any legislation—it is strictly a matter for adjustment by the General Staff at the War Department, and on recommendations made by the Surgeon-General it is now receiving consideration by that body. Unquestionably, inequality of promotion has been indirectly influenced in the past by disproportionate and unfair distribution of grades in existing tables of organization. During the war, whenever the question of promotion for a medical officer arose, it seemed extremely difficult to convince the deciding officer that promotion in the Medical Department had absolutely no connection whatever—as far as legal allowances were concerned—with any table of organization. Medical Department allowances are computed only on the total authorized enlisted strength of the army, and are expressed in one aggregate which, in turn, by the same law is proportionately distributed in the various grades. As mentioned above, tables of organization for Medical Department personnel concern only the War Department—not Congress—and represent merely an effort to foresee and provide for the needs of the specific unit concerned. In other words, they show the proper distribution of the legal allowance of medical personnel and provide for the army by congressional enactment. Quite the contrary situation exists for the line of the army, the basic organization of which is prescribed by Congress in terms of tables, plus certain allowances for a detached officers' list. Heretofore, the Medical Department has attempted to parallel the line system by recommending tables of organization for essential units and then pooling for general distribution and assignment as needed, the officers remaining after the requirements of these tables have been met. The Medical Department "pool" is analogous to the line detached officers' list. Previous tables of organization recommended by the Medical Department have not provided a proper proportion of officers in the higher grades for units serving

with an expeditionary force. This faulty distribution has resulted in throwing into the pool a relatively large and disproportionate number of officers in the field grades—in other words, the higher rank has been reserved for officers in the home territory to the corresponding disadvantage of officers serving in the theater of operations.

An effort is now being made by the Surgeon-General to remedy this condition by effecting a more harmonious equalization in distributing the grades authorized for all Medical Department officers and noncommissioned officers borne on the tables of organization. Any man serving in an expeditionary force should have an equal chance for promotion with those in the home territory. This parity can be maintained only through proper distribution of the legally authorized grades. Places with higher rank must be authorized for our officers who are serving at the front. Furthermore, by authorizing a fair proportion of higher grades in tables of organization for the Medical Department, army, division and other commanders will be automatically relieved of the handicap of which many of them complained during the late war: this with reference to their inability to recommend promotion of a man in their own command simply because a place apparently did not exist for him in tables of organization. This left many vacancies that were never filled, and denied to reservists the promotion to which they were legally entitled. If a generous commander, in an effort to reward meritorious service, recommended a medical officer for promotion, he stood a good chance of losing his services because of the necessity of transferring him elsewhere where a place for him under tables of organization could be found. In accordance with the principles enunciated above, the more important changes proposed in tables of organization now under consideration are: division surgeon to be a colonel; each battalion surgeon to be a major; sanitary train commanding officer to be a colonel; field hospital battalion commanding officer to be a lieutenant-colonel; medical laboratory section of sanitary train to be in charge of a major; evacuation hospital (750 beds) to have one colonel, two lieutenant-colonels, seven majors and twenty-six captains and first lieutenants, a total of thirty-eight; mobile surgical hospital (250 beds), one lieutenant-colonel, two majors and sixteen captains or lieutenants, total nineteen; base hospital (1,000 beds), one colonel, two lieutenant-colonels, seven majors, twenty-nine captains and lieutenants, total thirty-nine; convalescent camp (1,000 beds), one colonel, two lieutenant-colonels, two majors, twelve captains and lieutenants, total seventeen; camp hospital, one lieutenant-colonel, three majors, eight captains or first lieutenants, total twelve; hospital train, one major, three captains or first lieutenants.

CONCLUSION

In our opinion the methods now prescribed for enrolling, classifying, training, promoting and calling to active service the medical reserve of the country are far from satisfactory. The organization of the reserve must be revamped and based on more scientific principles. The plan we are proposing may not be ideal, but we offer it as an effective means for betterment. Discussion of any of the features of our proposition, particularly with reference to constructive suggestions for improving existing or prospective conditions, in the columns of this journal or by correspondence direct with the writers, is invited. If this article results in

concentrating a little more thought at large on this very important phase of our national preparedness, the principal object of the writers will have been accomplished.

Surgeon-General's Office.

THE BROAD TAPEWORM IN MINNESOTA

FURTHER FACTS AND CONSIDERATIONS

W. S. NICKERSON, S.D., M.D.

LONG LAKE, MINN.

The recent article by Riley¹ is important in calling attention to the frequency of occurrence of the broad tapeworm in Minnesota, and especially in putting on record evidence of two more cases of native infestation by *Dibothriocephalus latus*. I desire to call attention to some other facts overlooked or not considered in the paper of that author.

NATIVE FOCI OF INFESTATION

Four clear-cut cases of native infestation have been reported. The first of these is the case of Dr. O. W. Parker of Ely, Minn., reported by me in 1906.² This, Riley refers to as "the only recorded case . . . not clearly explicable on the theory that the parasite was an importation."

The second case was that of Dr. Olaf A. Olson of Minneapolis, demonstrated by me before Section F. (Zoology) of the American Association for the Advancement of Science in Minneapolis (1910) and briefly reported in 1911.³ As this report did not appear in a medical journal, it seems to have been unnoticed by physicians. Riley, who evidently intended to give full credit to my work, has also overlooked it. Under these circumstances I may be excused for quoting a part of it here.

This case occurred in a woman who was born and has always lived in Hennepin County, Minn., never having been out of the state except once for a visit in North Dakota. While there, she ate dried and smoked fish (otherwise uncooked), and it was soon after her return home that she experienced symptoms attributed to the tapeworm. The infection must therefore have occurred in America and from the eating of American fish.

The other two cases are those reported by Riley.¹ We have, therefore, four unquestionable cases on record in which the patient acquired the parasite in this country—in three of the cases definitely in Minnesota, in the other either in Minnesota or in North Dakota.

Stiles⁴ says that "it is probable that immigrants will infect the fish in some of our lake regions." The case of Dr. Parker (reported in 1906) demonstrated that this had already occurred before the publication of Stiles' prediction.

Riley claims that the general view of medical men is that "there is very little evidence at present to justify an assumption that native foci of infection exist in this country." However true this may have been in the past, it must be said that for the future any such view

1. Riley, W. A.: The Broad Tapeworm, *Dibothriocephalus latus*, in Minnesota, Additional Records, J. A. M. A. 73:1186 (Oct. 13) 1919.

2. Nickerson, W. S.: The Broad Tapeworm in Minnesota, J. A. M. A. 46:711 (March 10) 1906.

3. Nickerson, W. S.: Some Data Concerning *Dibothriocephalus latus* in America, with Report of a Second Case of Infection Acquired in the United States, Science 33:270 (Feb. 17) 1911.

4. Stiles, C. W.: Osler's Modern Medicine, 1:563, 1907.

on the part of physicians can no longer be justified on the ground of lack of evidence, but instead must be attributed to their lack of knowledge of the facts. In reality, the case of Dr. Parker was enough to establish absolutely the existence of one focus of infection in America. As the number of reported cases becomes greater, more definite knowledge will be gained concerning the extent and number of such foci.

FREQUENCY OF *DIBOTHRIOCEPHALUS LATUS* INFESTATION IN AMERICA

Riley quotes Stiles⁴ as stating that over thirty cases have been recognized in the United States, chiefly among foreigners. In 1911³ I reported:

I have collected from physicians reports of the occurrence of the fish tapeworm (*Dibothriocephalus latus*) of man in sixty-five cases, fifty-one of which were in Minnesota. But six of these have been previously mentioned in literature. The hosts in two cases were Swedes, in one a Japanese, in two native-born, and the others with few if any exceptions were Finns.

From my experience in collecting these instances I feel certain that Riley's belief that "there are sections of Minnesota in which it is by all odds the commonest of the large tapeworms of man" is absolutely correct. It may be further stated that this condition will be found in any region, whether in Minnesota or elsewhere, which has a predominance of Finnish immigrants in its population. Furthermore, I feel certain that any desired number of cases within reason could be obtained. The number reported was sufficient to establish the prevalence of the worm in Minnesota, and its special frequency among Finns. I did not continue the search for more cases.

I very much doubt that it is more abundant in Minnesota than in several other states in which the sources of the population and the conditions of life are essentially similar. It is quite possible that an equal amount of study of helminthologic conditions in adjacent states might show *D. latus* as abundant there as in Minnesota.

THE PAUCITY OF PARASITOLOGIC EVIDENCE IN HUMAN CASES

It is worthy of note that none of the four known cases of native infestation with *D. latus* was reported by the physician who treated the case, and in neither of the cases which I reported were the special significant facts secured by the attending physicians until at my request they made secondary investigations. I wish to recognize fully the courtesy of these gentlemen in getting these facts for me; but the essential and significant point is that the facts were brought to light only through the cooperation of a physician and a parasitologist. It seems a safe assumption that, had it depended on attending physicians to obtain the evidence, no case of native infestation would have been recorded and relatively few cases of *D. latus* infection would have been reported. And what is true of this human parasite is probably equally true of many or most other species. For parasitologic data our main reliance must be on parasitologists. Physicians have small interest in parasitic cases beyond relieving their patients from the unwelcome guests; and most of them have very meager knowledge of the parasites removed. All tapeworms are alike to them, and any data based on their determinations (diagnoses) are therefore of doubtful value. It is probably not overstating the case to say that helminthologic determinations made by physicians who have not also been trained as zoologists

are of no greater value than diagnoses of intra-abdominal conditions (for example, appendicitis) made by zoologists who have not also had a medical training.

As people suffering from parasites very naturally and properly go to physicians for treatment, it follows that few cases of animal parasitism in man come to the attention of parasitologists. Thus is explained the paucity of data on human parasitology in this country, and also the questionable accuracy of many of these.

PARASITOLOGISTS AS CONSULTANTS

Few physicians realize that about as much study and experience are required to make a competent parasitologist as to make a competent physician; and competence in one field no more implies competence in the other in one direction than in the reverse. To be both physician and parasitologist is as rare as to be both physician and lawyer. In view of these facts and of the greatly increased rôle which animal parasitism has been shown in recent years to play in the causation of human disease, it becomes important that cooperation between these two classes of scientific workers be brought about. The physician who has to treat a case of human parasitism needs the benefit of consultation with a parasitologist, although in most cases it would be no more necessary for the consultant to see the patient than it would for the pathologist who diagnoses a tumor removed at operation. But the proper diagnosis of the case is dependent on the report of the specialist in both cases, and the degree of special knowledge required is equally great. The importance of a reliable diagnosis is generally recognized in the tumor case but not in the parasite case.

A difficulty in securing to the physician such consultation arises from the fact that parasitologists are not as numerous nor so easily accessible as pathologists—just as cases calling for their services are probably not as common as those calling for the services of the pathologist. This difficulty may, however, be overcome. The zoologists of the Bureau of Animal Industry in Washington are ready at any time to make determinations and reports of human or other parasites sent them. Furthermore, in most state universities and in many other universities, colleges and agricultural colleges there is some competent member of the zoological department who would be willing to make determinations of human parasites and give any needed suggestions or advice at little or no charge.

STATE PARASITOLOGISTS

It would seem best, however, that the state university should be made a central clearing-house for all such cases within the state. Some member of the department of zoology should be appointed or recognized as state parasitologist on whom would fall the task of receiving, classifying and reporting on human parasites sent him. Notices should be sent out to physicians giving directions for preserving and forwarding specimens accompanied by proper data and offering them the benefit of free determinations and any needed suggestions. In this way opportunity would be provided for the gathering of useful knowledge which is now lost and statistics so gathered would have the advantage of reliability. Physicians would receive helpful direction and suggestions as to possible sources of infestation, prophylaxis and problems for investigation.

The main question is, Can physicians be made to realize their need for such aid as I have suggested, and will they take enough interest in the matter to send in the specimens?

Clinical Notes, Suggestions, and New Instruments

REPORT OF A CASE OF SEVERE HEAD TETANUS WITH RECOVERY*

KENNETH M. LEWIS, B.S., M.D., NEW YORK.
House Physician, Roosevelt Hospital

This case is presented as one not uncommon in the services of large hospitals today, and as showing the ready response to antitoxin even after the onset of symptoms.

History.—A Finn, aged 36, admitted at 2 p. m., Nov. 8, 1919, to the service of Dr. Evan Evans, nine days previously, while returning from work late at night, had been waylaid by several men, beaten about the head and robbed. When he regained consciousness next morning he found he had a large laceration of the left ear and scalp. The wound was sutured at a nearby hospital, but tetanus antitoxin was not administered, so far as could be ascertained. He returned to the same hospital during the following week for dressings. On the seventh day a friend noticed that the left side of his face was flattened; on the eighth day the flattening was more marked and the patient had difficulty in opening his mouth. On the afternoon of the ninth day he presented himself to the emergency department of the Roosevelt Hospital.

UNITS OF ANTITOXIN ADMINISTERED

Date	Subcutaneous	Intravenous	Intraspinal
Nov. 8	3,000 (2 p. m.)	8,000 (4:30 p. m.)	5,000 (5 p. m.)
Nov. 9			5,000 (10 a. m.)
Nov. 9			5,000 (4 p. m.)
Nov. 10			4,000 (2 p. m.)
Nov. 18	1,500		

Physical Examination.—There was a complete left facial paralysis of peripheral type and marked trismus, the patient being able to open his mouth not more than 1 cm. There was a deep laceration, 4 cm. in length, at the posterior aspect of the left ear and scalp, which had been closed with five horsehair sutures. There was a small amount of foul smelling, purulent discharge, and a diffuse redness and swelling around the wound. The pupils were equal, regular, and reacted sluggishly to light. The neck showed moderate opisthotonos. The superficial abdominal reflexes were present; there was a moderate Kernig reaction; the knee jerks were hyperactive but equal; Babinski reflex was ++; there was no ankle clonus, paralysis or stiffness. The temperature was 99.2 F., respirations 20, and pulse 80.

Laboratory Findings.—Urine tests were negative except for a trace of albumin. The blood showed: white blood cells, 14,000, with 81 per cent. polymorphonuclears; red blood cells, 5,000,000; hemoglobin, 75 per cent. (Sahli); Wassermann reaction negative. Bacteriologic: On the morning following admission, two stab cultures were made in glucose agar tubes from the deepest part of the wound. After twenty-four hours of incubation, growth had occurred along the stab, with the formation of gas. Smears from the culture showed numerous long, slender, gram-positive bacilli with a large clear spore at one end, which morphologically were *B. tetani*. There were also small, gram-negative bacilli present in large numbers. These were later identified as *B. coli*. Inoculation was made direct from the original stab culture into the root of the tail of a white mouse. The mouse died in fourteen hours with marked stiffening of the extremities.

Treatment.—1. General Measures: The accompanying table gives the number of units of antitoxin administered. It can be seen that the greater part of the antitoxin was given by the intraspinal method. In addition to this, 1,500 antitoxin units were applied locally to the surface of the wound for two weeks. The diet consisted of fluids, such as milk, cocoa and eggnog with the addition of large amounts of sucrose and lactose.

2. Local Measures: At the time of admission the sutures were removed and the wound opened wide. The following morning the wound was washed with hydrogen peroxid, then with 3.5 per cent. tincture of iodine, followed by 1,500 units of antitoxin, and a dry dressing was applied. The local treatment was not started until the culture had been taken. The wound was dressed each day with the foregoing routine. The injection of antitoxin along the course of the left facial nerve was taken into consideration, but was abandoned on the advice of Dr. Park of the New York board of health.

Clinical Course.—November 8, the patient was admitted.

November 9, he was stuporous, and complained of pain at the site of the intraspinal injection; trismus was complete; opisthotonos was more marked; no vertebral motion was possible.

November 10, the Kernig and Babinski reflexes were more marked and the knee jerks more active. There was bradycardia; pulse from 50 to 60.

November 11, the knee jerks were less active, with the left greater than the right. The Babinski reflex was maximal. Herpes simplex appeared on the lips and the external nares. The patient complained of being stiff all over.

November 14, trismus and opisthotonos were decreasing and the neck was not so rigid. The knee jerks were feeble, with the left greater than the right. Kernig's sign and bradycardia were still present.

From this time on the patient began to show a gradual diminution in the signs. The trismus and opisthotonos gradually decreased in severity. The knee jerks, however, again became very active on November 15, and remained so in decreasing proportion until November 25. The Babinski and Kernig reflexes became negative, November 17, and on this day the neck and back were freely movable. The facial paralysis did not show signs of returning function until November 22; December 1, the facial paralysis was still present but there was daily increase in function, and the trismus had entirely disappeared. The wound was allowed to heal by granulation with frequent dressings and became entirely closed by Jan. 1, 1920. At no time during the course of the disease was there a local or general convulsion, and the patient did not seem especially sensitive to external stimuli. There was a slight fever on the second day, but none subsequently. The patient was finally discharged, with a slight remnant of the facial paralysis but with no other symptoms.

ACUTE VERONAL (BARBITAL) POISONING: REPORT OF A CASE

S. J. TAUB, M.D., CHICAGO

History.—Mrs. G. E., a married white woman, aged 28, had been accustomed to using from 10 to 20 grains of barbitol almost every night during the last two years following a hysterectomy for fibroids. Her health had been good except for attacks of nervousness and insomnia. Three days previous to my visit, she ate some shrimp salad in a restaurant and became suddenly ill two hours later, with nausea, vomiting, abdominal pains and diarrhea. On advice of her husband that night she took 50 grains of barbitol, purchased in the form of 5-grain "veronal" tablets, in order to get some sleep. The vomiting was much less but the diarrhea continued through the night and the patient felt stuporous, drowsy and very weak. During the next day she took 100 grains of barbitol again in order to sleep off the effects of what she called ptomain poisoning from eating shrimp salad.

Examination.—I saw her the evening of the same day, Dec. 24, 1919. She was in bed and appeared seriously ill; she was in a stuporous condition and answered questions very slowly. Her voice was very faint and had a prolonged, drawing expression. There was some confusion but no disorientation. The face had an ashy gray hue and the lips were very pale.

The nails were cyanotic and she complained of being very cold. The temperature was 97.5, pulse 52, and respiration

* From the Medical Wards of the Roosevelt Hospital.

12. The pupils were dilated and reacted to light and accommodation. The tongue was heavily coated and the breath fetid. The heart was regular in action and slow (52). The skin was cold and dry, and it presented a slight yellowish hue.

The patellar, triceps and biceps reflexes were very sluggish. Sensibility for pain, touch, heat and cold was about normal. On attempting to walk to the bath room, she staggered and had to be assisted. There was a marked ataxia of both the lower and upper extremities. She could not hold anything in her hands.

Treatment and Result.—The patient was immediately given an ampule of camphor in oil, 1 c.c., into the deltoid muscle. An attempt was made to pass a stomach tube, but this was impossible because of the patient's poor condition. Strychnin, $\frac{1}{50}$ grain, every two hours, alternating with atropin sulphate, $\frac{1}{100}$ grain, was given by mouth. Heat was applied externally to keep up the body temperature.

December 25 the patient was somewhat improved, although the diarrhea continued and she felt very weak. Lethargy and drowsiness persisted and she slept at intervals but was easily aroused. The ataxia had not disappeared.

There was typical hematoporphyrinuria, December 25, which persisted for three days, until December 28. After the fourth day, December 26, she was able to sit up in a chair, but the ataxia persisted until December 29, the end of one week.

1204 East Forty-Seventh Street.

REPORT OF CASE OF INTUSSUSCEPTION WITH GANGRENOUS APPENDIX IN EIGHT MONTHS OLD BABY

ROBERT K. BUFORD, M.D., HANSFORD, W. VA.

History.—A well nourished girl, aged 8 months, referred by Dr. G. S. Hartley, while sitting up in bed playing, commenced crying with severe abdominal pain, which was evidently of paroxysmal character, and was followed by vomiting. The child became pale and listless. The bowels had moved three times during the day; the last stool was normal and contained no blood. On palpation of the abdomen, a tumor mass was found in the right hypochondriac region. The body assumed a position of opisthotonos following another sudden paroxysm of pain. Rectal examination was negative. Blood and mucus, but no fecal matter, were obtained by enemas. A diagnosis of intussusception was made and the baby was brought to the Sheltering Arms Hospital within thirty-six hours after the onset, and I saw her, in consultation with Dr. Hartley, and confirmed his diagnosis. A tumor mass was demonstrated by fluoroscopic examination.

Operation and Result.—A right rectus incision was made under ether anesthesia. An ileocecal intussusception was found, the ileum being invaginated into the cecum, which was pushed up into the ascending colon. The appendix was gangrenous throughout. The involved intestines were injected but showed no gangrene. There was some free fluid, serous in character, in the peritoneal cavity. The blood supply of the obstructed intestine was not impaired. The intussusception was reduced by a slow general milking process; the appendix was removed and the wound closed in the usual manner without drainage. The operation was performed in twenty minutes, and the baby was awake before leaving the table.

Postoperative treatment consisted in the prevention of reverse peristalsis, and in stimulation, nourishment, and combating intestinal toxemia. Plain morphin sulphate was given as indicated, beginning with $\frac{1}{120}$ grain and in increasing quantities every hour until $\frac{1}{16}$ grain was reached. Then as a routine measure, this drug was continued in doses of $\frac{1}{16}$ grain every four hours for the first seventy-two hours. The toxins were counteracted by proctoclysis and hypodermoclysis of physiologic sodium chlorid and 5 per cent. glucose solutions, respectively.

No nourishment was given by mouth for the first thirty-six hours, after which time, breast milk was fed every two hours in one-half ounce feedings. This was continued until the morning of the fourth day, when the child was put to the

breast and allowed to nurse ten minutes every four hours until the mother began menstruating. Artificial feeding was then resorted to until the subsidence of all menstrual phenomena; at alternate periods it was given all the distilled water it would take.

The wound healed by first intention and the baby was discharged from the hospital three weeks after operation.

USE AND ABUSE OF CATHARTICS*

(Continued from page 393)

PURGATIVE PILLS

PODOPHYLLUM

Podophyllum was introduced by the "eclectics" during the period when these practitioners endeavored to substitute drugs of "kindly" action for those drugs, used by the "regular school," that were harsh and dangerous when employed without the necessary admixture of brains. Calomel was anathema to them, and not without cause. So they hunted for a substitute for this drug, and believed they had found it in podophyllum, which came to be known as the "vegetable calomel."

One of the points in which podophyllum resembles the mild mercurous chlorid is the comparative insolubility of its resinous active principles in the acid stomach and their solubility in the alkaline intestinal secretions. As in the case of calomel, its action seems to be especially exerted on the upper portion of the small intestine. Thus, Ringer quotes some dog experiments by Anstie in which it was found that, after injection of an alcoholic solution of resin of podophyllum into the peritoneal cavity, the small intestine, especially toward the lower end of the duodenum, was extremely congested; and, in some instances, the lower part of the duodenum was extensively ulcerated. The large intestine was but slightly engorged. Although the injections were poured into the abdominal cavity, the peritoneum itself was not at all inflamed, even around some unabsorbed granules of the resin.

Mode of Action.—Podophyllum is an irritant to skin and mucous membranes. It tends to act as a purgative even when applied to ulcers or raw surfaces, or when given hypodermically, though the local irritation produced precludes its practical employment in this manner. It must be classified as a drastic cathartic in view of the fact that overdosage produces gastro-enteritis. A sufficiently small dose, from 0.003 to 0.006 gm. ($\frac{1}{20}$ to $\frac{1}{10}$ grain) of the resin, produces merely laxative effect; in doses of 0.008 to 0.030 gm. ($\frac{1}{8}$ to $\frac{1}{2}$ grain) this resin is an active purge. A single dose of 0.05 gm. (1 grain), or a daily dose of 0.10 gm. ($1\frac{1}{2}$ grains), as a general proposition should not be exceeded. Excessive dosage may produce bloody and slimy stools, especially in children. It may occasion, even in medicinal doses, considerable colic and sometimes nausea. Podophyllum has little tendency to produce after-constipation. Hence it is suitable for prolonged use.

* This is the eighteenth of a series of articles on the pharmacology, physiology and practical application of the common laxatives and cathartics. The first article appeared October 18.

Unfortunately, it is a rather uncertain cathartic, a dose, adequate to purge one person violently, being inoperative in another. Its dosage, therefore, should be small at first and gradually increased as necessary. Likewise does the time required for action vary from a few hours to twelve or twenty-four hours or more. Combination with some other agent, such as aloes, might rectify some of these defects.

Indications.—Podophyllum is worth a trial in cases of "biliousness," especially those of the frequently recurring type, in which the repeated administration of calomel would be contraindicated because of danger of mercurial poisoning. The syndrome of "biliousness" need not be present in its full evolution. Thus, certain types of sick headache are relieved by agents of this class better than by anything else. So may certain cases of periodically recurring attacks of indigestion. As podophyllum cannot possibly act as an antiseptic—an action that, as we have seen, is doubtful in case of calomel—a more suitable explanation for the special value of the "chologogues" in "biliousness" than that based on the theory of antiseptic action might be built on Alvarez's¹ theory of "reverse peristalsis." He believes that the syndrome of biliousness is produced by a focus of excessive irritability in a lower portion of the digestive tube, for instance, a chronically inflamed appendix, which upsets the normal gradient of irritability that should become progressively less as we proceed from above downward. Now it is not unreasonable to assume that some of these purges, with special action on the upper portion of the small intestine, might, by increasing the irritability of the duodenum and jejunum, restore the previously upset "gradient of forces." This is merely offered as a working hypothesis for experimentation. It cannot as yet be even dignified with the term theory.

Method of Administration.—The resin of podophyllum is the only preparation of this drug that should be employed. The name "podophyllin" has been applied to this mixture of alcohol-soluble and water-insoluble principles. In view of the desirability of limiting the ending "in" to pure principles, the use of this word in the present popular sense is unscientific, and should be abandoned. Let us remember that habits of speech produce and reflect habits of mind.

Resin of podophyllum may be prescribed in the form of a 1:60 alcoholic solution (1 grain to the dram), one or two drops of which may be given on a lump of sugar to children, three or four drops to adults. It is usually given in the form of pills. However, the nicest way of giving it is in the form of tablet triturates, each containing 0.0006 gm. ($\frac{1}{100}$ grain), one or two of which may be given every hour for from four to ten doses.

COMBINATION OF ALOES AND PODOPHYLLUM

As podophyllum is one of the slowest of all cathartics in action, combination with rapidly acting purgatives is irrational, as is also the case with aloes. On the other hand, combination of podophyllum with aloes impresses one as rational, not only because of similarity in time required for action, but also because of difference in point of chief attack. An experiment should be devised—and might easily be performed by classes of medical students—to test the question whether we have in such combination a real case of heterotopic synergism. Should a patient present a combination of the special indications for these two cathartics, they might be

suitably combined in one pill. The National Formulary contains a formula for such a pill under the name, *Compound Pills of Aloes and Podophyllum*, each of which contains:

Aloes	Gm. 0.065	gr. 1
Resin of podophyllum	0.0325	gr. $\frac{1}{2}$
Extract of belladonna leaves	0.016	gr. $\frac{1}{4}$
Extract of nux vomica	0.016	gr. $\frac{1}{4}$

For reasons given in a previous article, the last two ingredients might as well be omitted. Not only are they useless, but they might do harm, the belladonna by producing dryness of the mouth, and the nux vomica by increasing the reflex excitability and "nervousness" in neurasthenics. But why give the patient a "hand-me-down" article at any time, when he comes to us for individual measurement and fit? Not only is this not best for the patient, but it is even worse for the physician. By getting into the lazy habit of prescribing ready-made preparations, he loses in aptitude and power of devising combinations of his own. How miserably dependent we become when we practice prescribing according to formularies will be painfully evident to the routine C. C. pill and A. S. and B. pill prescriber, who might desire to reform. But it is worth the effort; and the attempt to get out of the rut should be made before a sclerotic condition of habits of thought and action have made such a change impossible.

(To be continued)

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, SECRETARY.

CHLOROXYL.—Cinchophen hydrochloride.—Phenylcinchoninic acid hydrochloride $C_{16}H_{19}NCOOH.HCl$. The hydrochloride of 2-phenyl-quinoline-4-carboxylic acid.

Actions, Uses and Dosage.—The same as that of cinchophen (see New and Nonofficial Remedies, 1920, p. 224) Phenylcinchoninic Acid (Cinchophen) and Phenylcinchoninic Acid Derivatives.

Manufactured by Eli Lilly and Co., Indianapolis, Ind. U. S. patent No. 1,306,439 (June 10, 1919; expires, 1936).

Chloroxyl Tablets 5 grains.—Each tablet contains chloroxyl 0.325 Gm. (5 grains).

Chloroxyl is a yellow crystalline powder with an astringent, slightly bitter taste. It is insoluble in water, ether or chloroform, but slightly soluble in alcohol.

When dry, chloroxyl melts at about 223 C.

Accurately weigh about 2 Gm. chloroxyl, add 250 Cc. half-normal volumetric sodium hydroxide solution and heat on a boiling water bath for one hour. Determine the excess of sodium hydroxide by titration with half-normal hydrochloric acid volumetric solution, using phenolphthalein as indicator. Chloroxyl contains not less than 12 per cent. nor more than 12.8 per cent. combined hydrochloric acid (each Cc. sodium hydroxide solution is equivalent to 0.00912 Gm. HCl).

Dissolve 2 Gm. chloroxyl in 10 Cc. solution sodium hydroxide: heat to boiling, and while hot add acetic acid until no further precipitate is formed. Cool, decant the supernatant liquid and wash the precipitate with distilled water until it is free from acetic acid. Dry the precipitate at 100 C. This precipitate responds to the U. S. P. tests for phenylcinchoninic acid.

Inexpensive Breakfast Food.—DR. J. G. GRANT, Akron, Ohio, writes: Most people are now interested in reducing the high cost of living. For those who use wheat breakfast food, I have a suggestion, after having tested this plan more than a year: Buy wheat from a farmer or dealer and grind it in a coffee mill or food grinder. For two dollars I bought a spice mill, which is larger than a coffee mill. This food is excellent and many times cheaper than that sold in packages.

EFFECTS OF QUININ ON THE TISSUES

There are circumstances in which the vigorous action of adequate quantities of quinin in the circulation is highly desirable. The alkaloid itself is rather insoluble; but some of the salts of quinin are fairly soluble, and are absorbed with considerable readiness from the gastro-intestinal canal. The Pharmacology of Useful Drugs,¹ issued by the American Medical Association, makes it seem probable that too much importance has been attached to the influence of the degree of solubility of the salts of quinin on their absorption, and too little attention to the selective capacity of the gastro-intestinal tract for absorbing them. In the United States, in contrast with European countries, quinin sulphate is the salt generally prescribed, although the hydrochlorate is decidedly more soluble and ought to be preferred. However that may be, numerous endeavors have been made to secure more effective quinin therapy, particularly in malaria, by modes of administration other than the usual oral path.

Bacelli first suggested the intravenous injection of solutions of salts of quinin when the symptoms of malaria are so severe as to threaten grave peril to the patient. Subcutaneous or intramuscular injection has also been recommended and frequently employed, particularly in critical cases. Despite the use of care in giving such treatment, much discomfort and pain may be caused; and even if aseptic precautions are studiously applied, a considerable amount of induration if not actual abscess formation is likely to occur at the site of injection. Most therapeutists recognize this danger and warn against it.

That tissue necrosis is produced by strong solutions of quinin salts need not be a surprise when it is recalled that for more than half a century the substance has been regarded by toxicologists as a protoplasmic poison capable of destroying various forms of animal and vegetable cells. The suggestion has at times been made that, because of the observed tissue damage following intramuscular injections, this mode of administration should be abandoned. A recent experimental inquiry

by Colonel Dudgeon² of the British Army Medical Service on the effects of injections of quinin into the tissues throws new light on the actual conditions developed by the procedure. It had been suggested that in order to avoid the untoward results, intramuscular medication should be carried out only with dilute solutions. Dudgeon points out, however, that injection of quinin in solutions so dilute as to avoid edema and tissue necrosis is not of practical utility in man. Concentrated preparations of quinin produce more intense necrosis than do dilute ones; but when the latter are such as to be of therapeutic value, they also excite the tissue changes at the site of infection.

A concentrated solution of quinin is absorbed rapidly from the tissues even in patients who are moribund. Dudgeon insists on the necessity of realizing that tissue necrosis—spreading edema and local blood destruction—are produced by the solvents frequently employed for quinin administration; and the effects are only slightly inferior to those excited by the quinin salts and the alkaloid. No advantage was gained by the addition of oil or by injecting the alkaloid dissolved in alcohol or ether. Necrosis of blood vessels in the area of injection is a common result. This leads, according to Dudgeon, to hemorrhages into the tissues. Extensive damage of these sorts in the neighborhood of an important nerve trunk may result in nerve palsy.

It may be that a choice between disadvantages will dictate the continuance of intramuscular injections of quinin. If so, the limitations and dangers of their use in practice need to be appreciated clearly and specifically. Daily doses administered for periods of a week and more in the gluteal region—a favorite site of injection—are not unknown. Such cases have been found, further, to retain only fragments of healthy tissues in the muscular tracts involved. Hence one can appreciate the force of Dudgeon's warning that repeated intramuscular injections of quinin should not be given into the same area of muscle or tissue directly adjacent, because otherwise permanent injury of muscle or nerves may result.

THE MENTAL CONDITION PRECEDING SUICIDE

It is a curious but well substantiated fact, commented on some time ago in THE JOURNAL,³ that there are fashions in suicide just as there are in almost every other human activity. Indeed, the fashion changes not only with regard to the methods employed for terminating existence, but also in the whole attitude of peoples toward suicide. In the days of the ancients, suicide was not regarded as a crime. The Stoic school of philosophy taught that every person had the right to decide whether or not to continue in this life.

In the United States alone about 10,000 persons annually terminate their existence by self destruction.

2. Dudgeon, L. S.: On the Effects of Injections of Quinin into the Tissues of Man and Animals, *J. Hyg.* 18: 317 (Oct.) 1919.

3. The Style in Suicide and Homicide, Current Comment, *J. A. M. A.* 73: 1367 (Nov. 1) 1919.

1. Hatcher, R. A., and Wilbert, M. I.: Pharmacology of Useful Drugs, Chicago, American Medical Association, 1915.

This large number of deaths naturally brings up the question of the prevention of suicide, which in turn leads to a consideration of its causes. Since self destruction is no longer countenanced by public opinion, the number of suicides has decreased considerably, and it is safe to assume that persons seldom resort to the procedure unless they are mentally abnormal or unless there are strong reasons of an unpleasant nature. Certain psychiatrists, Forbes Winslow, for example, have held that invariably persons who commit suicide are mentally abnormal; but there is little doubt that this view is not correct. In the case of criminals, particularly, there is evidence of deliberate suicide by persons perfectly capable of understanding the nature of the act. The fact remains, however, that in existing circumstances the majority of those who take their own lives are mentally abnormal. Recently Brend,⁴ in discussing the mental condition preceding suicide, has shown that probably 50 per cent. of all such persons are definitely insane, and that most of these are suffering from melancholia, chronic alcoholic insanity, or the hebephrenic form of dementia praecox. The statistics from certain European army hospitals indicate that patients suffering from psychoses, particularly those of the manic-depressive type, are much more likely to commit suicide than patients suffering from neuroses. Neurotic persons frequently discuss suicide and express fear that they will do away with themselves, but they hardly ever reach the point of actually attempting self destruction. Figures quoted by Brend show that among 3,700 patients suffering with neuroses there were only one suicide and two unsuccessful attempts, whereas among 3,000 patients suffering from psychoses there were three successful suicides and 105 unsuccessful attempts. It is tolerably clear, therefore, that a considerable proportion of all suicides occur in mentally abnormal persons.

The question of the prevention of suicide is intimately associated with the early detection and treatment of insanity. At present, agencies for the early detection and treatment of insanity are conspicuous chiefly by their absence. This is true not merely in the United States but throughout the world. Some progress has been made in combating this condition by the establishment of psychopathic hospitals and by the educational efforts of bodies like the National Committee for Mental Hygiene and its allied state committees; but material progress will not be made until the public has been educated to a more acute appreciation of the importance of the early detection of mental disease, and until the facilities for the early treatment of mental cases under voluntary commitment to a hospital for the insane have been widely extended. It is quite certain that more widespread education in mental hygiene would result in a reduction in the number of suicides.

AMEBIC DYSENTERY IN THE UNITED STATES

Scarcely thirty years have elapsed since Osler¹ published what is believed to be the first report in this country of a case of dysentery in which amebas were found in the stools. Not long afterward, Lafleur² reported another case and demonstrated the living parasites. Welch remarked on this occasion that it was the second case of dysentery reported on this continent and the first exhibit of the organism before a medical society in this country.

We have been inclined to regard intestinal amebiasis as something belonging to the tropics and foreign to the United States. The disorder has consequently been expected only in persons who have recently returned from tropical countries. Nevertheless, amebic dysentery has been by no means unknown in the Southern United States, and sporadic cases have been reported from time to time in New England, as well as in the Eastern, Central and Western states. In 1909, Patterson³ collected records of the disease in twenty-four states, many of them in the Northern sections of the country. Since then practically all of the states have been shown to harbor patients with amebiasis.

Although this type of dysentery has rarely been epidemic in temperate climates, occasional outbreaks have been known to occur, as for example in the German army in East Prussia in 1901.⁴ More recently, the special examinations of the feces of very large numbers of persons for intestinal parasites have directed attention anew to the possibility of the existence of amebiasis in this country to an extent formerly unsuspected. Instructive instances have been furnished by the division of parasitology of the California State Board of Health.⁵ As a result of a circular letter to forty-five hospitals at points widely distributed throughout the state, a total of fifteen cases of amebic dysentery was reported from eight of these institutions. Out of seventeen cases there were at least six in which the disease seems to have been contracted in California. If a necessarily cursory survey brought to light such a number of cases, it can scarcely be doubted that amebiasis is more prevalent than the identified instances directly indicate.

The situation is complicated further by the undoubted existence of carriers who reveal absolutely no dysenteric symptoms, yet harbor the parasitic organism in some form. Although the motile stages of *Endameba dysenteriae* are very sensitive to change and cannot readily withstand conditions outside of the hosts, this

2. Lafleur: Demonstration of Amœba Coli in Dysentery, *Bull. Johns Hopkins Hosp.* 1: 91 (Sept.) 1890.

3. Patterson, H. S.: Endemic Amœbic Dysentery in New York, with a Review of Its Distribution in North America, *Am. J. M. Sc.* 138: 198, 1909.

4. Strong, R. P.: Amebic Dysentery, cited in Osler's *Modern Medicine* 1: 489.

5. Cort, W. W., and McDonald, J. D.: Amebic Dysentery in California, *J. Infect. Dis.* 25: 501 (Dec.) 1919.

is not equally true of the cysts of the organism. When the latter are voided with the feces, they are apparently very resistant. They survive for considerable periods in water; and this fact is important in relation to the spread of amebiasis. Ordinary bacterial examination of water will not reveal the presence of endamebic cysts. The water may carry contamination to garden produce as well as directly into the drinking supply.

The California investigators, Cort and McDonald,⁵ have pointed out that countries with long, dry seasons or those with long periods of temperature below the freezing point will find in natural conditions a considerable check on the distribution of amebiasis. However, conditions might occur in almost any country at almost any time under which there would be sufficient moisture and a high enough temperature to make possible the transfer of the cysts in a viable condition from one person to another. On the other hand, as Cort and McDonald further point out, California is unique in having certain conditions favorable to the spread of amebic dysentery. Within the state are large numbers of people from countries where the disease is prevalent, many of whom are undoubtedly carriers. A large majority of these raise garden produce, or become cooks and domestic servants. The state also has extensive irrigated areas that are seldom, if ever, visited by a freezing temperature for a considerable period. California is also uniquely situated with respect to the introduction of the disease. Yearly there have come in a large number of immigrants, the greater part of whom have settled in the state. These immigrants have come principally from Japan, China and India, where intestinal protozoa are common.

WHAT IS SO-CALLED SCIENTIFIC DRINK CONTROL?

The legal controversies and the debates that have been initiated by the enforcement of nation-wide prohibition in the United States have unexpectedly emphasized that many of the essential facts regarding alcohol and its action are not yet known to science. This is surprising, in view of the extent to which alcohol has been and still is being consumed by man. Nevertheless, it is true that there exist scarcely any manuals which may be referred to by the general reader for authoritative statements of unbiased expert opinion regarding a subject of such widespread interest. Most of the evidence is tinged either with the prejudice of the temperance fanatic or the insidious propaganda of ex parte influence.

The markedly lowered death rate from alcoholism following the legal prohibition of alcoholic beverages in one of our largest American cities was recorded recently in *THE JOURNAL*.¹ In Great Britain the lessened number of convictions for drunkenness follow-

ing the decreasing sale of alcoholic drinks during the war period has frequently been cited. It is becoming evident throughout the civilized world that either the most objectionable results of drinking must be eliminated by some sort of reform or else the prohibition wave is certain to sweep beyond the shores of the Atlantic. Thus the problem of drink regulation has been brought into new relief. The chairman of the Central Control Board for Liquor Traffic in England, Lord D'Abernon,² has thus expressed the hope of the reformers who face the alternative of liquor suppression:

If by the method of regulation on physiological principles we can secure adequate results for the health and sobriety of the nation, these results will be attained with less apparatus, with less risk of creating alternative evils, with less loss of revenue, with less disturbance of trade and less abrupt violation of the habits of the community.

Prohibition as a national possibility has still for the most part to demonstrate its results and its limitations in this country. It is a new social experiment on a huge scale. Meanwhile we may do well to examine judiciously the scientific basis of some of the proposals of those who would regulate rather than prohibit the liquor traffic. Aside from the irritant action of concentrated solutions on the mucous membranes, the pharmacologic or toxicologic effects of alcohol depend primarily on the concentration which it attains in the circulating blood. The Advisory Committee of the Central Control Board in London, including scientists of recognized talent, has directed the investigation of the comparative effect of identical doses of alcohol in dilute or concentrated solutions, respectively. The outcome showed that with dilute solutions the maximum level of alcohol in the blood is lower than when the drug is taken in concentrated form.

The bearing of this on the difference between alcohol in the forms of beer, wine and distilled liquor is obvious. But it was further demonstrated that the same amount of alcohol taken in the form of beer was decidedly less intoxicating than spirits diluted to contain the same dose of alcohol in equal volume. The reason is not demonstrated; but since beers contain ingredients other than alcohol, it is presumably allied to the well known fact that alcohol taken with foods is absorbed more slowly than when it is drunk on an empty stomach. The cocktail and analogous drinks are thus condemned on physiologic principles.

Lord D'Abernon, who presumably speaks with the authority of large groups of conservative Britons, has also discussed the plan of discontinuity of drinking hours—a device, somewhat comparable to the preferment of dilute alcoholic beverages, intended to decrease the evils of drunkenness simply by diminishing the amount of liquor drunk at one time. Experience in Great Britain has unexpectedly disclosed that restricted

1. Prohibition and the Death Rate, editorial, *J. A. M. A.* 74: 109 (Jan. 10) 1920.

2. D'Abernon: The Scientific Basis of Drink Control, Address at the Autumn Conference of the Society for the Study of Inebriety, Oct. 14, 1919; *Brit. Jour. Inebriety* 17: 73 (Jan.) 1920.

hours for liquor traffic do not accomplish the end sought.

The oxidation and elimination of alcohol proceed at only a moderate rate. According to Mellanby's experiments, the quantity of alcohol included in 2 pints of beer—about 45 c.c. of alcohol—requires an interval of three or four hours before it is completely burned or excreted. Superimposing an extra dose of alcohol within the interval brings the risk of inebriation. Lord D'Abernon points out that no benefit will result, therefore, through drinking less concentrated alcoholic beverages at intervals curtailed and regulated by law, if liquors of high alcoholic content can be consumed within the limited period.

We are told that it is more important to regulate how a nation drinks than how much it drinks. One may accept the principles of the use of drinks of low alcoholic content and the regulation of drinking hours, perhaps so as to make them coincide more nearly with meal hours, as the essential conditions for any promising system of drink control short of prohibition. But it remains to be demonstrated that rationing beer, or restricting the opening hours of the saloon, or any other governmental system short of the elimination of the liquor traffic, will accomplish for human welfare what is expected of prohibition in the United States. Nowadays scientific experiments are being conducted on a national scale.

Current Comment

NEW TARIFF ON DYE PRODUCTS

An event of uncommon interest to the medical profession is the amendment adopted by the subcommittee of the Senate Finance Committee to the bill placing a duty on dyes imported into the United States. This amendment places a tariff of 45 per cent. on the higher saccharids, adonite, arabinose, dulcitol, galactose, inosite, inulin, levulose, mannitol, mannose, melizitose, raffinose, rhamnose, sorbitol and xylose. Prior to the war these chemicals came exclusively from Germany. Their manufacture in this country started as a result of stoppage of importations. Medical officers of the army succeeded in having these chemicals manufactured in the United States, and this protective tariff will, it is believed, save this industry and permit its future development. The tariff was advocated by Professor Stieglitz, chairman of the Committee on Synthetic Drugs of the National Research Council, by Colonel Reasoner, in charge of the field medical supply depot at Washington, and by Colonel Russell of the Army Medical School. Colonel Russell said:

"Many of the rare sugars are used in bacteriology in the differentiation of various disease-producing micro-organisms. It is a well established fact that certain bacteria as, for example, the bacillus of typhoid fever, use certain sugars and from them produce acids and other products which we can measure or detect if present only in small amounts; some organisms, such as the colon bacilli, produce not only acid, but gas, which is caught in a fermentation tube, measured

and analyzed. The differentiation of the real from the pseudo-organisms of diphtheria and some other diseases depends on sugar fermentations and on animal experiments.

The quantities used in any one test are quite small but a large variety, and a good supply of the principal sorts is indispensable, and we should not be satisfied to rely in the future on other countries for products of such fundamental importance, but should aid the growing industry which is now being organized in the United States.

SPEAKING OF GLANDS—

Although the glands of internal secretion have been a source of interest to the medical profession for some time, it is only recently that the attention of the lay public has been called to these structures. During the recent illness of one of our noted statesmen, widespread discussion of one of these glands was common, even in polite society. The subject was considered from every possible point of view, and it is doubtful whether there is any well-informed person today who has not some vague idea of the functions of this particular structure. Later, sensational newspapers made much of the discovery—if it should be called such—of the Frenchman Voronoff, that the interstitial cells of the testes might be used to stimulate growth, and as the newspapers would have it, perpetuate youth. Little has appeared in scientific literature concerning this point. However, Macht¹ has just reported that feeding of prostate gland tissue to tadpoles resulted in stimulation of the metabolism, hastening metamorphosis, with the further result that the size of the tadpoles was not diminished, but in many cases actually increased. This effect was produced by feeding the desiccated prostate of the ram, the bull and also that of human origin. It has been known for some time that feeding of thyroid tissue also hastens metamorphosis. In the case of the thyroid, however, there is a shrinkage or dwarfing in the size of the tadpoles as contrasted with the observation that prostate feeding produces increased size and more rapid growth. Controlled experiments made with other desiccated glands fail to produce a similar effect. We are thus beginning to gain an inkling of knowledge regarding certain growth-producing factors of the human organism. One may yet see "gland fathers" and "gland mothers."

WHAT IS THE MATTER WITH ARKANSAS?

Arkansas evidently still elects to be the dumping ground for quacks, charlatans and half-baked medical practitioners coming from schools not recognized in the majority of states. A legislative effort was made recently to secure a new practice act by which this could be prevented, but the bill was killed. Instead of having a single board with a reasonable minimum standard of educational qualifications for those who are to obtain the legal right to treat human disorders, Arkansas has at present divided the authority among six different boards. It now has not only a regular board of medical examiners but also a homeopathic board, an eclectic board, an osteopathic board, a chiropractic board and an optometry board. Any other cult

1. Macht, D. I.: On the Effect of Prostate Feeding on the Development of Tadpoles, *J. Urol.* 3: 411 (Oct.) 1919.

seeking recognition could doubtless easily secure it in the wide open and generous state of Arkansas. Through the eclectic board in Arkansas, a low grade so-called eclectic medical school in Kansas City, the Kansas City College of Medicine and Surgery, not recognized in Missouri—its home state—continues to exist, since its graduates have easy entry into Arkansas. Through the existence of the several boards, others may prey on the public of Arkansas without first obtaining reasonable qualifications of preliminary and medical education. How long are the people of Arkansas going to stand for such flimsy protection against ignorance and incompetence? Do they appreciate the fact that they themselves are and will be the sufferers?

DEATHS FOLLOW THE EATING OF RIPE OLIVES

The death of six persons in Memphis, Tenn., following the eating of ripe olives, with a fatal prognosis in a seventh case, are reported in the General News department in this issue. Investigation has already revealed the fact that these deaths were due to *Bacillus botulinus*, the olives being packed by the "cold pack" method. The brief report thus far available indicates that the food product in question was a part of a salvaged stock and that the olives when found possessed a noticeably pronounced foul odor. Deaths have previously been reported from the same source in Canton, Ohio, Detroit and New York, and wide prominence has been given to the fact that all of these deaths followed the eating of ripe olives. And yet there will no doubt continue to be persons who will eat noticeably spoiled food, just as there are persons who attempt to outrace railroad trains over grade crossings, persons who step off moving street cars backward and some who refuse vaccination against smallpox.

COMMERCIAL DOMINATION OF BIOLOGIC THERAPEUTICS

The danger of commercialized therapeutics has been enormously increased by the introduction of biologic products. These substances offer a rich field for the commercially minded, first, because of the remarkable results which seem to have followed the use of certain products of this type; second, because the field is new and the mode of action of these substances not readily understood and, third—and most important—because, by the very nature of the problems involved, few physicians are well informed concerning them. The influenza epidemic of last year was widespread and fatal in character. It stimulated earnest research in methods of prevention and cure. We were all in a frame of mind to grasp at any straw. Here and there some worker would cry "Eureka"—only to be disappointed when his product was actually put to the test. However, there were more than enough manufacturers ready to place any product on the market with specious claims that could not be positively denied. Vaccines, serums, proteins—all were advanced with such glowing statements as to their properties that only those physicians who kept their

feet firmly on solid ground could resist the appeal. Now we have had another epidemic—mild, it is true—but the memories of last year make the average physician ready to accept anything which promises hope, and the manufacturers—"make hay while the sun shines." Physicians have been and are being deluged with literature on the prophylaxis and treatment of influenza. So far as we know, few publications have contained any word of warning on these matters. One exception has just come to notice: the *Medico-Military Review*, a semimonthly mimeographed publication sent to medical officers of the Army by the Surgeon-General's Office. This says:

YOU ARE REMINDED that so far a comprehensive analysis of results obtained by the use of monovalent and polyvalent vaccines in the prevention of influenza has not demonstrated their value. Much carefully controlled experimental work is now being carried out on this subject both in civil institutions and in the Army, and any worthwhile advances will be reported in the *Review* from time to time. If a prospective vaccine is developed, it will be prepared at the Army Medical School for general distribution and all medical officers will be duly notified. The general use of the present commercial polyvalent protective against influenza is not considered desirable. Numerous telegrams and other requisitions are being received for influenza vaccine. In view of the fact that no prophylactic influenza vaccine is available, such requisitions should be discontinued.

Association News

ELECTIONS BY BOARD OF TRUSTEES

Council on Pharmacy and Chemistry

At the annual meeting of the Board of Trustees held at the headquarters of the Association, February 6, Drs. F. G. Novy, Ann Arbor, Mich.; G. W. McCoy, Washington, D. C., and George H. Simmons, Chicago, were elected members of the Council on Pharmacy and Chemistry.

Editorial Boards of Publications

The following were elected members of the editorial boards of the special journals published by the Association as indicated: Dr. Joseph L. Miller, Chicago, *Archives of Internal Medicine*; Dr. Fritz B. Talbot, Boston, *American Journal of Diseases of Children*; Dr. Frederick Tilney, New York, *Archives of Neurology and Psychiatry*, and Dr. Samuel T. Orton, Iowa City, to fill the unexpired term of Dr. August Hoch, deceased, *Archives of Neurology and Psychiatry*.

THE NEW ORLEANS SESSION

Hotel Reservations for the New Orleans Session

The chairman of the Local Committee on Hotels, Dr. J. J. Wymer, 1216 Maison Blanche Building, New Orleans, urges those who plan to attend the annual session of the Association at New Orleans, April 26 to 30, to make hotel reservations promptly. (For hotel headquarters see THE JOURNAL, Jan. 10, 1920, p. 110.) The Committee on Hotels will gladly assist those who do not secure reservations at the hotel of their choice to arrange for comfortable lodgings.

By Boat to New Orleans

The schedule of the Southern Pacific Steamboat Line announces a boat to leave New York on Saturday, April 24, and to arrive in New Orleans at 9 a. m. Wednesday, April 28. The boat will lie at the Canal Street Pier, New Orleans, until Saturday, May 1. Passengers may make arrangements so that they may occupy state rooms for the three days on which the sections meet. In this way, they will be assured of comfortable lodgings while at New Orleans.

Dr. Ira J. Haynes, P. O. Box 24, Richmond, Va., who is arranging parties to go by boat to New Orleans, reports that already he has received a number of inquiries indicating interest in the proposed excursion, and wishes to learn as promptly as possible how many desire to join these parties in order that definite arrangements may be completed. Tentatively, he estimates that the time necessary for the round trip by boat will be about, but not over, two weeks; that the cost of the trip will be practically equivalent to railroad fare and the cost of sleeping car accommodations and meals. If the demand warrants, one party will sail from New York and another from some point on Chesapeake Bay. The latter will stop at Old Point Comfort and Havana. The plans are that these boats shall arrive at New Orleans on Tuesday afternoon in time for the General Meeting, the opening meeting of the Scientific Assembly, and the passengers will occupy their state rooms during the time of the annual session. While in New Orleans, breakfast may be obtained on the boat.

Pullman Sleeping Cars May Be Parked at New Orleans

Physicians from different points are planning to charter Pullman coaches which will be parked practically in the center of the city so that they may be occupied during the time of the annual session. This use of Pullman coaches is common at the Mardi Gras and other large gatherings in New Orleans. It provides reasonably comfortable lodgings at moderate rates. Parties starting from different points may charter a Pullman car and retain it throughout the session, in this way being assured of comfortable accommodations on the going and returning trip as well as while in New Orleans. The terms, including the charges, may be obtained from the railroad ticket office at the point from which such parties will start for New Orleans.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSAS

Baby Clinic at Little Rock.—The United Charities Association, Little Rock, has opened a baby clinic at the Armory City Park, where a nurse is in attendance from 1 to 3 p. m. to instruct mothers on the care of babies. On Wednesdays from 1 to 2 p. m. babies will be weighed and examined by the physician in charge. When babies are too ill to be brought to the station the nurse will visit the home.

Hospital News.—Governor Brough has issued a proclamation calling on the people of the state to support the campaign for raising \$300,000 for the erection of a children's hospital in Arkansas. Plans for the hospital have been completed. It will be of fireproof construction throughout. The site for the hospital has not been selected.—Through the cooperation of the city and the Medical Department of the University of Arkansas, the free dispensary in the Isaac Folsom Clinic Building, Little Rock, has been reorganized and reopened. A pharmacy, a laboratory and a roentgen-ray department have been installed, and a clinical clerk has been employed.

ILLINOIS

Cost of Influenza.—The state director of health estimates that the influenza-pneumonia epidemics of 1918 and 1919 have cost the people of Illinois more than \$125,000,000. The value of the life of an adult is placed at \$3,000 and that of a child at \$500. During the year ended June 30, 1919, there were 223,683 cases of influenza and pneumonia, with 25,222 deaths.

Chiropractor Serving Jail Sentence.—Mrs. Emma Calvin of Monticello is now serving a jail sentence for violating the medical practice act. Mrs. Calvin is a member of the Illinois Association of Chiropractors, and the secretary of the association, with headquarters at Joliet, has sent out a letter to other chiropractors urging that Mrs. Calvin be supplied with reading matter during her incarceration.

Personal.—Dr. Albert R. Trapp, Springfield, is reported to be seriously ill with pneumonia.—Dr. Charles E. Dorr, Worden, was recently attacked on the street by a coal miner and sustained fractures of the nasal and one of the malar bones.—Dr. William H. Grayson, Granite City, the oldest member of the Tri-City Medical Society, was the guest of honor at a banquet given by that organization, January 23.

What Medical Freedom Advocates Want.—The advocates of "medical freedom" propose the following as a section of the bill of rights in the contemplated new constitution of the state of Illinois: "The free exercise and enjoyment of the profession and practice of the art of healing, without discrimination shall be forever guaranteed; and no person shall be denied any of his opinions in the field of that art; but liberty of conscience hereby secured shall not be construed to dispense with sanitation in the sense of cleanliness, or excuse acts of licentiousness, or justify practices inconsistent with the peace and safety of the state. No person shall be required to obey, or to pay taxes to support, any practitioner or any system of healing against his consent, nor shall any preference be given to any school or system of healing."

Chicago

Joint Meeting.—At a joint meeting of the Chicago Medical Society and Chicago Pathological Society held February 11, papers were read by Dr. Harry Gideon Wells, on the "Pathological Characteristics of Tumors in Mice, and Their Relation to Human Tumors," illustrated by lantern slides, and by Dr. Maude Slye, on "The Inheritability and Biological Characteristics of Tumors," illustrated by charts.

Indictments.—Indictments were returned by the Federal Grand Jury, January 21, against William H. Sage, former head of the narcotic division of the Internal Revenue Bureau, Dr. Joseph A. Greaves and Hyman Cohen, proprietor of the William H. Sage Drug Co., charging them with violation of the Harrison Narcotic Law.—Dr. Anna B. Schultz is reported to have been arrested, January 23, charged with writing wholesale prescriptions for liquor.

MAINE

Work of State Laboratory.—More than \$36,000 was saved to the people of Maine during 1919, through 10,000 free tests made by the diagnostic laboratory of the state department of health at Augusta, of which Dr. Herbert E. Thompson, Augusta, is director and Mrs. Ruth Patten is biologist. Of these tests 5,837 were made for venereal disease; 1,063 for diphtheria; 1,827 for tuberculosis; 380 for typhoid; 243 for malignancy, and the remainder for miscellaneous conditions.

New Officers.—At the fifty-first stated meeting of the Cumberland County Medical Society, Dec. 12, 1919, Dr. Francis J. Welch, Cumberland, was elected president; Dr. Daniel Driscoll, Cumberland, vice president, and Dr. Erastus E. Holt, Jr., Cumberland, secretary-treasurer.—York County Medical Society held its ninety-ninth annual meeting in Biddeford, January 7, and elected Dr. Frank W. Smith, York Village, president; Dr. Paul S. Hill, Saco, vice president; Dr. Arthur L. Jones, Old Orchard, secretary, and Dr. Carl G. Dennett, Unity, treasurer.

Venereal Disease Clinics.—Five free clinics for persons suffering from venereal disease who are unable to pay for treatment have already been established in the state. These are at the Augusta Health Center with Dr. George A. Coombs, in charge; at the Mason Dispensary, Portland, with Dr. Gustav A. Pudor, in charge; at the Eastern Maine General Hospital, Bangor, with Dr. Harrison J. Hunt, in charge; at the Bath Health Center, with Dr. Langdon T. Snipe, in charge, and at Dr. Miner's hospital, Calais, with Dr. Walter N. Miner in charge. Clinics will soon be in operation at Rockland and Waterville.

Public Health Work.—Under the direction of Dr. Leverett D. Bristol, Augusta, commissioner of health, a new era of public health work opened in Maine this year when the state was divided into eight health districts with a full-time district health officer in each district. With one exception the new district officers were physicians, qualified both by general practice and by previous health work in their various communities. The new officers are Dr. Clarence F. Kendall, Biddeford; Dr. James W. Loughlin, Damariscotta; Dr. Guy H. Hutchins, Presque Isle; Dr. Edward P. Goodrich, Lewiston; Dr. John F. Stevens, Millinocket; Dr. Henry D. Worth, Bangor, and Alton S. Pope of Waterville.—Legislation went into effect, January 1, providing that a local health officer, either for full or part time, shall be employed by

every community or group of communities in Maine, and such appointments are slowly being made in the different towns, subject to the approval of the commissioner.

MARYLAND

New Officers.—The Caroline County Medical Society at its annual meeting elected Dr. Stephen S. Stone, Ridgely, president, and Dr. John R. Downes, Preston, secretary-treasurer.

Personal.—Dr. George F. Sargent has purchased property near Towson, which he will open as a sanatorium.—Dr. William E. Martin, Harrisonville, who has been ill has recovered and resumed practice.—Dr. Ida M. Kahn of China, in charge of the first woman's hospital at Nanchangfu, and for two years in charge of a hospital for women at Tientsin, spoke at a meeting at the Y. M. C. A. in Baltimore, February 8, on her work in China.

Hospitals Crowded.—Baltimore hospitals, with one exception, are crowded to their capacity with patients. The only hospital whose public ward is not crowded is the Johns Hopkins, the largest in the city. Dr. William L. Moss, Baltimore, president of the Maryland Hospital Conference Association, sounded a warning to the community in reviewing the situation, as the condition is growing more critical every day, with the danger from the spread of influenza and pneumonia. At the office of the supervisors of city charities, where patients may be designated to the free wards, it was said that the situation never had been so serious. The closing of the two colored wards at the Maryland General Hospital because of a shortage of nurses constitutes another serious problem in the hospital situation, as it affects the care of the colored patients.

MISSOURI

Porter Addresses Academy.—Dr. John L. Porter, Chicago, delivered an address before the Kansas City Academy of Medicine, February 13, on "Differential Diagnosis of Chronic Joint Diseases."

Personal.—Dr. Emmett McD. Bridgford, Santa Fe, is reported to be critically ill.—While a grand jury at Kansas City, January 15, was considering criminal charges against him, Dr. John W. C. Boone, Kansas City, is reported to have shot and wounded the husband of the woman who had preferred the charges.

License Suspended.—For soliciting patronage through agents in violation of the medical practice act, the state board of health is said to have suspended the license of Dr. Oscar A. Young, Excelsior Springs, for a period of one year from Nov. 10, 1919. Dr. Young appealed to the circuit court of Clay County which sustained the action of the board.

NEW YORK

State Aid for Tuberculosis.—The legislature has been asked to appropriate \$1,000,000 for state aid to tuberculous patients. The bill proposes to license boarding houses in the country for the care of tuberculous patients, and to assure medical supervision and proper sanitary conditions.

Personal.—Dr. Thomas B. Carpenter, Buffalo, has been appointed director of laboratories of the department of health of Buffalo to fill the place of Dr. William G. Bissell, deceased.—Dr. George R. Little, Schaghticoke, has been elected and Dr. Stanton P. Hull, Petersburg, reelected a member of the board of directors of the Rensselaer County Tuberculosis Association.

Semicentennial of Society.—The semicentennial anniversary of the Jenkins Medical Society was celebrated at the New York Athletic Club, January 8. Dr. Henry Moffat, Yonkers, presided as toastmaster, and addresses were made by a number of prominent physicians of New York City. The membership of the society is made up of physicians of Mount Vernon and Yonkers.

Postgraduate Course at Albany.—A course in infectious diseases and public health will open at the Albany Medical College, March 4, and sessions will be held each Thursday until the last week in April. An additional day will then be devoted to practical demonstrations, and thereafter the class will be in session on Thursdays and Fridays until June 18. The course will be in charge of Dr. Charles C. Duryee, Schenectady, to whom all communications and applications should be made.

Appropriation to Fight Influenza.—A call on the legislature, February 2, for an appropriation of \$50,000 to combat

the influenza epidemic, met with instantaneous response. From January 23 to February 2, there were reported to the state department of health, 799 cases of pneumonia, with 139 deaths, and 5,850 cases of influenza, with twenty-one deaths. Advices received at the department of health indicate that influenza is prevalent in rural districts and in Syracuse, Jamestown, Poughkeepsie, Mount Vernon and Albany.

New York City

Venereal Disease Lectures.—During the month of December, audiences totaling 3,400 men and women attended forty-three lectures on venereal diseases given under the auspices of the division of lectures of the bureau of public health education.

County Society Discontinues Prosecution of Illegal Practitioners.—Owing to the expense incident to this work the Medical Society of the County of New York has taken action discontinuing the collection of evidence and the prosecution of cases of unlawful medical practice. Hereafter all cases of unlawful practice which, in the opinion of censors, require investigation or prosecution, will be reported to the police department of the city and the district attorney for action.

Establish and Protect Priority to Medical Discoveries.—At a meeting of the section on historical medicine of the New York Academy of Medicine, February 4, a committee composed of Dr. Robert T. Morris, Dr. Thomas L. Stedman and Dr. A. L. Soresi suggested the creation of a special medical board that should establish and protect the priority of ideas relating to medical subjects. This board should correspond to the patent office; it should patent in its name all new surgical instruments and pay a royalty to the inventors, much as publishers deal with writers of medical books.

Associated Physicians of Long Island Elect.—At the twenty-second annual meeting of the Associated Physicians of Long Island, January 31, the following officers were elected: president, Dr. Henry Goodwin Webster, Brooklyn; vice presidents, Drs. Harris A. Houghton, Bayside, Hugh Halsey, Southampton, and Joshua M. Van Cott, Brooklyn; secretary, Dr. James Cole Hancock, Brooklyn, and treasurer, Dr. Edwin S. Moore, Bay Shore. Following the scientific session a dinner was served at the Montauk Club, after which addresses were made by Father John L. Bedford, Brooklyn; Hon. Walter C. Burton, postmaster, Brooklyn, and the Hon. Regis H. Post, ex-governor of Porto Rico.

OKLAHOMA

Tuberculosis Clinic Organized.—Under the direction of Drs. William E. Lamerton, Julian Field and the public health nurse of Garfield County. Enid has opened a free tuberculosis clinic.

New Officers.—At the annual meeting of the Central Oklahoma Medical Association held in Enid, January 20, Dr. William H. Rhodes was elected president, and Dr. Harry F. Van Dever, secretary-treasurer, both of Enid.

Personal.—Dr. Francis B. Fite, Muskogee, has been unanimously selected by the city commissioners to fill the vacancy as mayor.—Dr. Dock Long, Duncan, has been appointed chief physician of the bureau of tuberculosis of the state department of health.—Dr. and Mrs. David A. Myers, Lawton, were seriously injured in San Antonio, Texas, January 6, in a grade crossing accident in which their automobile was struck by a train.—Dr. James C. Hawkins has been appointed health officer of Blackwell, succeeding Dr. Arlington R. Havens, resigned.

OREGON

Woman Appointed Deputy Health Officer.—Dr. Emma Maki Wickstrom, Portland, has been appointed deputy health officer of Multnomah County and has been assigned to duty with the court of domestic relations.

Hospital Item.—Owing to the need of more hospital space in Portland it is reported that the building at East Second and Multnomah Streets which was begun several years ago will be converted into a hospital of about 100 beds.

New Officers.—At the annual meeting of the Coos-Curry County Medical Society Dr. George Earl Low, Coquille, was elected president and Dr. Philip J. Keizer, North Bend, secretary.—The Portland Ophthalmological and Otolaryngological Society at its annual meeting elected the following officers: president, Dr. John F. Beaumont, Portland; vice presidents, Drs. Sherman E. Wright and Ralph A. Fenton, Portland, and secretary-treasurer, Dr. C. Gertrude

French, The Dalles.—At the annual meeting of the Central Willamette Medical Society which includes Linn, Benton and Lincoln counties, in Albany, December 5, Dr. Robert Bruce Miller, Lebanon, was elected president; Dr. Robert A. Jayne, Philomath, vice president; Dr. Robert L. Wood, Lebanon, secretary-treasurer.

PENNSYLVANIA

New Secretary-Editor.—At the meeting of the council of the Medical Society of the State of Pennsylvania, Dr. Frederick L. Van Sickle, Olyphant, was elected executive secretary and will be the editor of the *Pennsylvania Medical Journal* beginning with the July issue.

Epidemics.—The department of public health has instituted active measures for combating the threatened epidemic of influenza. A letter has been sent to each physician emphasizing the necessity of prompt report of all cases of influenza and pneumonia. The health authorities of Erie have taken possession of the government dormitories at Fourth and Cascade Streets for use as an emergency hospital during the prevalence of scarlet fever.

Arrest of an "Association Doctor."—Alleged to be one of the smoothest "quacks" operating in this country, Dr. John Newhall Kirk was arrested, February 6, by chief county detective, Major S. O. Wynne, at the instance of Dr. Edward Martin, the state health commissioner. At the same time a fugitive warrant from Baltimore was served on the physician. Dr. Kirk was operating here as elsewhere under the name of "Association Doctors."

Philadelphia

Mary Scott Newbold Lecture.—Dr. Alonzo E. Taylor delivered the third of the Mary Scott Newbold lectures before the College of Physicians, February 6, on "Post War Conditions and Problems of Civic Organization in Europe."

New County Officers.—At the business meeting of the Philadelphia County Medical Society, held January 21, Dr. Herman B. Allyn was elected president; Dr. Benjamin F. Devitt, vice president; Dr. James Morton Boice, secretary; Dr. Charles Scott Miller, assistant secretary, and Dr. Edward A. Shumway, treasurer.

Packard Lecture.—Sir Arthur Newsholme, M.D., K.C.B., lecturer of public health administration, School of Hygiene and Public Health, Johns Hopkins University, delivered the annual Frederick A. Packard Lecture of the Philadelphia Pediatric Society in Thompson Hall, College of Physicians, February 10, on "Neo-Natal Infant Mortality."

Campaign for Woman's Medical College.—The campaign to raise \$250,000 as an extension fund for the Woman's Medical College of Pennsylvania is two thirds completed, as the result of an intensive drive from January 8 to January 20. On March 11, the seventieth anniversary of the founding of the college will be marked by special exercises, and the building will be open to the public. Five teams organized by women interested in social and civic welfare are working for a \$60,000 memorial fund as a tribute to the late Dr. Anna Howard Shaw.

VIRGINIA

Health Department Issues Bulletin.—The health department of Norfolk has initiated a monthly digest of its activities, in which current health problems are discussed.

Personal.—Dr. Ira H. Thomas, Aldie, has retired on account of ill health, after thirty-one years of practice. Dr. Joseph E. Taylor has been appointed city coroner of Danville, succeeding Dr. Edward H. Miller, Jr., Danville, resigned.

Influenza.—Up to January 28, 1,001 cases of influenza had been reported in Richmond, with only four deaths. An appropriation of \$10,000 to combat influenza was asked from the finance committee of the Richmond city council, January 27, by health officer, Dr. Ernest C. Levy.

Society Reorganized.—The Southwest Virginia Medical Society was reorganized at a meeting held recently at Pulaski. Meetings of this organization had been suspended since 1916. The membership of the organization includes residents of the counties of Pulaski, Montgomery, Wythe, Smyth and Washington. Members of the profession from counties contiguous to those included and from the cities of Roanoke and Bristol are eligible as associate members.

Dr. Wilson R. Cushing, Dublin, was elected president; Dr. Joseph A. Noblin, East Radford, vice president; Dr. Alfred B. Greiner, Rural Retreat, secretary-treasurer.

WASHINGTON

Personal.—Dr. Ralph Hendricks, Spokane, was reelected health officer and secretary of the health board of Spokane, January 9. Dr. James T. Mason, Seattle, has been appointed a member of the state board of health succeeding Dr. Henry H. McCarthy, Spokane, term expired. Dr. Claude A. Lewis, Fairfield, has been elected mayor of Fairfield. Dr. Richard Connell, North Yakima, has been appointed physician of Yakima County. Dr. Charles C. Benedict, Enumclaw, has been appointed local surgeon for the Milwaukee railway system.

New Officers.—Lewis County Medical Society at its annual meeting, Dec. 8, 1919, elected Dr. James M. Sleicher, Chelalis, president; Dr. Frederick J. Hackney, Centralia, vice president, and Dr. Rush Banks, Centralia, secretary. Whatcom County Medical Society at its annual meeting elected the following officers: president, Dr. Hays A. Compton, Bellingham; vice presidents, Drs. Albert M. Dawson, Bellingham, Charles S. Hood, Ferndale, and Carl C. Hills, Custer; secretary, Dr. Edward L. Brinson, Bellingham. King County Medical Society at Seattle, January 8, elected as president, Dr. Homer D. Dudley; vice president, Dr. Herbert E. Coe, and secretary-treasurer, Dr. Howard J. Knott, all of Seattle. Spokane County Medical Society at Spokane, January 8, chose as president, Dr. Arthur T. R. Cunningham; vice president, Dr. James D. Windell; secretary, Dr. Fred G. Sprowl; corresponding secretary, Dr. Edward S. Jennings, and treasurer, Dr. John H. R. Brodrecht, all of Spokane. By a vote of 65 to 30 the society denied the right of any member to engage in contract work.

WEST VIRGINIA

Personal.—At the fourth annual meeting of the West Virginia State Hospital Association, at Parkersburg, Dr. Joseph A. Guthrie, Huntington, was unanimously reelected president of the organization.

State Society Meeting.—At the meeting of the Little Kanawha and Ohio Valley Medical Society in Parkersburg, January 20, it was decided that the annual meeting of the West Virginia State Medical Association be held at Parkersburg, May 18 to 20.

WISCONSIN

Personal.—Prof. Henry C. Tracy, A.M., Ph.D., Milwaukee, has been appointed professor of anatomy in the University of Kansas, Lawrence and Rosedale.

Office Building for Physicians.—The Beloit Physicians and Surgeons Club, January 16, inaugurated a movement toward securing an office building, medical laboratory, and club room for physicians and dentists, to cost \$100,000. A committee consisting of Drs. Arthur C. Helm and Harry E. Burger was appointed to take charge of this matter. At this meeting, Dr. Arthur C. Helm was elected president, Dr. Virgil D. Crone, vice president, and Dr. Benjamin Fosse, secretary-treasurer.

CANADA

Personal.—Dr. James Third has resigned as professor of medicine in Queen's University, Kingston. Dr. Harold P. Rogers, Toronto, has returned after four years' service in Mesopotamia and Syria. Dr. Alfred K. Haywood, medical superintendent of the Montreal Hospital, has been appointed chairman of the committee of the Canadian National Council for Combating Venereal Disease. The council will interest physicians throughout Canada in the venereal disease problem and in plans of the Dominion government for its solution. Dr. C. M. Sellery, Toronto, who served overseas in England and France, has been appointed a medical missionary in China, and will take up his work in August. Dr. John Noble has been elected chairman of the Toronto Board of Construction.

GENERAL

Secretary Houston Requests Appropriation to Combat Plague.—Secretary of the Treasury Houston, in a communication to Congress, has requested supplemental appropriation in the sum of \$250,000 to enable the Public Health

Service to continue its work of controlling the outbreak of bubonic plague discovered in New Orleans last October. Since that time the Public Health Service has been spending \$50,000 monthly to effect suppression and control of this disease.

Appreciation of Work of Rockefeller Institute.—The Rockefeller Institute for Medical Research has received a letter from Surgeon-General William C. Braisted, U. S. Navy, testifying to his appreciation of the valuable aid rendered by the institute in connection with the War Demonstration Hospital, New York City. The assistance was not limited to the active period of the war, but continued after the signing of the armistice and indicated a high standard of efficiency in the institute both as to personnel and equipment.

Bequests and Donations.—The following bequests and donations have recently been announced:

Montefiore Home, Hebrew Orphan Asylum, Sanatorium for Hebrew Children, Blind Asylum of New York, Skin and Cancer Hospital, Servants for the Relief of Incurable Cancer, Beth Israel Hospital and Henry Street Nurses' Settlement, all in New York, each \$3,700 by the will of Emma Feuchtwenger.

Clarence Barker Memorial Hospital, Biltmore, N. C., a gift of \$50,000, from Mrs. Walker Rathbone, Bason.

Columbia University for the equipment of surgical research laboratories, an anonymous donation of \$6,000.

Grace Hospital, Toronto, \$500 by the will of the late Dr. Charles E. Treble, Toronto.

Boat Trip to Mississippi Valley Conference.—The Mississippi Valley Conference on Tuberculosis will be held at Duluth, Minn., September 2, 3 and 4. The Mississippi Valley Council has chartered the S. S. *North American*, which will leave Chicago, August 30, and returning will reach Chicago on the morning of September 7. The cost of the trip, including war tax, sleeping accommodations and breakfasts in Duluth, will be \$80. The only additional expense will be luncheons and dinners at Duluth during the three days of the meeting. Reservations may be made on application to Mr. James Minnick, superintendent of the Chicago Tuberculosis Institute, 8 South Dearborn Street, Chicago.

Recommendations Regarding Yale School of Medicine.—After a study of a survey and report as to the School of Medicine of Yale University, Dr. Fred T. Murphy presented his views to the committee on educational policy, which unanimously recommended the following minutes which have been adopted by the corporation:

1. That there is a clear and definite opportunity and obligation of the university to medical education.
2. That the Yale School of Medicine has a valuable nucleus of men and material and sound traditions, which rightly justify the development of an institution for medical education of the highest type.
3. That the corporation accept as a policy the development of a medical school of the highest type to include the pre-clinical and clinical years of instruction upon such principles of medical education as may be approved by the corporation, after conference with the medical faculty.
4. That every effort be made to obtain at the earliest possible date the necessary funds with which to expand and develop the buildings, the equipment, the instruction, and the research, and the service, in accordance with the best ideals of modern medical education—as an essential unit of our university plan for development.

A Modern Almanac.—The Miners' Safety and Health Almanac for 1920 (Miners' Circular 26), compiled by the U. S. Public Health Service, has just been issued by the Bureau of Mines of the Department of the Interior. This is the second year that the Bureau of Mines has issued this calendar. In addition to the usual information, it contains instructions on the prevention of various diseases and accidents, and shows the miner how he can reduce the risks of his occupation. He is told that sickness means loss of time and money, and that it may mean reduced efficiency or permanent incapacity. There are special articles on influenza and pneumonia, miners' consumption, miners' nystagmus, contagious diseases among children, prevention of coal dust explosions, malaria, flies, typhoid fever, pure drinking water, school inspection, adenoids, "patent medicines," venereal diseases, sanitary housing, dust and ventilation in mines, mine gases and sanitary privies. The reader is advised that "patent medicines" are unnecessary, useless and a waste of money; that frequent and routine physical examinations are a good thing; that clean drinking water is just as essential as clean food, clean air or clean homes. The booklet is copiously illustrated and well printed. Thus the almanac, formerly a medium for the dissemination of misinformation regarding "patent medicines," has become also a worthy agency in providing accurate information on the prevention of accidents and disease.

Botulism from Eating Ripe Olives

Newspapers of February 8 reported deaths following the eating of ripe olives, this time in Memphis, Tenn. Previous deaths occurred in Canton, Ohio, Detroit and New York, and have been reported in THE JOURNAL. THE JOURNAL asked Dr. B. W. Fontaine, associate professor of medicine in the Memphis Medical College, for an account of these cases. He telegraphs the following report:

"Thursday afternoon, February 5, at a luncheon given by a weekly social club at the home of Mrs. M. V., there were three guests, the hostess and a 10 year old boy. Later on the husband of the hostess and the husband of another guest joined the party, making seven in all, each person partaking of the refreshments. The first illness, the case of Mrs. H., began ten to twelve hours later, death occurring some time Friday morning, Mrs. H. being found dead in bed at 8:30 a. m. The next death was the hostess, Mrs. V. on Saturday morning at 5 a. m.; the third death, another woman, Saturday afternoon; the fourth, the husband of Mrs. V., Saturday afternoon; the fifth, another guest, Sunday morning; the sixth, the 10 year old boy, Sunday afternoon. The last guest is now seriously ill and is not expected to survive, making six deaths and the seventh case probably fatal. The initial symptoms were referred chiefly to the throat and eyes; the most noticeable symptoms were sensations of constriction about the throat and inability to swallow. Double vision soon occurred in all the cases and was finally followed by blindness. No gastro-intestinal symptoms occurred, except in the case of the boy, who was slightly nauseated. In all of the cases respiration was extremely labored and the pulse was very fast. Prostration was extreme, the temperature was subnormal. All of the patients were entirely conscious to the time of death. Necropsies were not permitted.

"Investigation by the health department discloses the fact that the menu at the luncheon consisted mainly of ham sandwiches, lettuce salad and whole ripe olives. No alcoholic liquors were drunk. Investigation of the jar from which the olives were taken showed that it had contained about fifty olives. Nine olives were found in a dish on the table. It is estimated that each guest must have eaten from four to six olives. The olives were of ripe variety, packed by the cold process in brine and were in a glass jar, having a tin top with a rubber seal under the cap, bearing the number 3X3602, put on by a rubber stamp. Just below the top, around the neck was a paper band, bearing the word 'Jumbo.' On the main label, just below the band were the words: 'Supreme Curtis Olives Corporation, Los Angeles, U. S. A.' In the middle of the label, in large type were the words: 'Curtis quality, 16 ounces net' and a picture of three or four large black olives. The olives found in a dish on the table had a very objectionable and pronounced foul odor. In the kitchen, on the drain-board was found the empty jar containing about twelve drops of the brine, which also gave the same disagreeable odor. The olives were obtained from a store in Memphis of which the principal business is buying and selling salvaged merchandise. The olives were transported by the firm from one of their branch houses in Montgomery, Ala. Investigation reveals that many cases of the same brand of olives were sold by this house. Ten or twelve jars were still unsold, which had finally reached Memphis. Examination of the olives by the city chemist and bacteriologist showed them to be soft and black and to have been preserved in brine. The contents of the other jars, similar to the jar in question, and put up by the same company, bearing the same label and packing number were without odor and wholesome so far as gross appearance was concerned.

"Bacteriological studies in the limited time, necessarily being hurried and incomplete, have revealed an anaerobic motile bacillus, gram positive, morphologically and culturally identical with *Bacillus botulinus*. Injection of the original brine in minute quantity, about one hundredth of a cubic centimeter subcutaneously, into a guinea-pig resulted in death in nine hours, with symptoms of labored respiration, ruffling of the hair and dilatation of the pupils, the four feet outstretched."

FOREIGN

Mortality of Lisbon.—It is stated from Lisbon that the mortality for the year 1918 exceeded that of any previous year. The number of deaths was 17,071 or 5,543 more than the previous year. The number of deaths caused by the influenza was 3,692; seven deaths were due to typhus fever. No mention is made of the death rate.

Prize for Orthopedic Research.—The Rizzoli Orthopedic Institute at Bologna, Italy, announces that the competing articles or appliances sent in to compete for the Umberto I prize of 3,500 lire must be in the hands of the president of the institute before Dec. 31, 1920. The prize is awarded for the best work or invention in the field of orthopedics and competition is open to physicians of all countries. The provisions for the competition will be sent on demand. Address the President, Instituto ortopedico Rizzoli, Bologna, Italy.

Surgeons Form Association.—Surgeons representing the surgical staffs of all the great teaching hospitals of Great Britain assembled in London, January 8, under the chairmanship of Sir Rickman J. Godlee, London, and organized the "Association of Surgeons of Great Britain and Ireland," thus following the precedent set by members of the medical staffs several years ago. The association will be representative of British surgeons, will represent British interests at international surgical congresses and will foster scientific meetings of surgeons from time to time at various centers. Sir John Bland-Sutton, London, was elected president of the association.

Physiology at the Paris Aviation Show.—The sixth Salon de l'aéronautique, which was held at Paris the last week in December, was a striking demonstration of the progress in the medical side of aviation since the last Salon in 1913. Two sections were devoted to physiology; one more especially civilian and aeronautical, the other essentially military and devoted to the study of aviation in general. It had six subsections showing the general examination of the candidate for aviation, the examination of the nervous system and the senses, a full display being made of the instruments and apparatus used in the various tests. Among the exhibits in the subsection for examination of circulation and respiration were much enlarged photographs of the blood pressure and pulse curves showing the effect of fatigue on athletes and aviators. The various devices for studying and overcoming the effect of rarefaction of the air included Dr. Garsaux's automatic oxygen inhaler. This supplies 35 liters an hour per person, and automatically increases this supply progressively up to 150 liters at 8,000 feet. The Salon exhibited further data showing that there are now fourteen companies of aerial navigation in France and that between May and November, 1919, they had a record of 1,079 voyages, covering 442,180 kilometers and carrying 1,356 passengers, without the loss of a single person. The organizers of this physiology exhibit were Dr. Cronzon, a leader in the medical features of aviation, and Dr. M. de Fossey, who is styled by the *Journal de médecine de Bordeaux*, in its report of the exposition, "the *cheville ouvrière* of this remarkable medical exposition."

LATIN AMERICA

Quarantine Against New Orleans Lifted.—It is stated from El Salvador that the quarantine affecting all ships from New Orleans has been lifted.

Dr. Lefás Goes to Paraguay.—Dr. Emmanuel Lefás, of Paris, has accepted the chair of pathology in the school of medicine of Paraguay, and will arrive in Paraguay about the middle of February.

Personal.—Dr. B. K. Ashford, Col., M. C., U. S. Army, of Porto Rico, has been visiting in Cuba. Sessions in his honor have been held by the Association of the Medical Press of Cuba and the Society of Clinical Studies.

New Nurses' School at Nicaragua.—Dr. Luis Sequeira, of Bluefields, Nicaragua, is about to establish a school for nurses in that city. There will be only twelve pupils admitted at first and teaching will be free of charge.

Election of Officers.—The Sociedade Brasileira de Neurologia, Psychiatria e Medicina Legal recently elected its officers for the new year: president, Prof. J. Moreira; vice president, Prof. Abreu Fialho, and secretary-general, Dr. M. Pinheiro.

Medical Students in Cuba.—The number of students enrolled in the School of Medicine and Pharmacy of the University of Havana during the year 1919-1920 is 1,560,

distributed as follows: medicine, 1,037; pharmacy, 312; dentistry, 170; veterinary 41.

Deaths in the Profession.—Dr. Horacio Rodríguez, aged 36, was the first victim in the profession to succumb to typhus during the prevailing epidemic of typhus at Valparaíso, Chile. He was connected with the Asistencia Pública, in direct charge of typhus patients, and leaves a widow and two children.

Health Certificates for Colombian Travelers.—The office of public health of Colombia has issued regulations decreeing that passengers traveling on outbound ships must be provided with a physician's certificate to the effect that they are not suffering from any contagious disease.

Medical Society of Caracas.—At a recent meeting held by the medical society of Caracas the following officers were elected: president, Dr. J. Sanabria Bruzual; vice president, Dr. B. Perdomo Hurtado; treasurer, Dr. Andrés Pietri; secretary, Dr. Jiménez Rivero; librarian, Dr. Salvador Quintero, and editor of the journal, Dr. Salvador Córdova.

New Leprosarium.—A model leper hospital, equipped to accommodate several hundred patients of both sexes and all ages, is being built some distance outside the city of São Paulo. Well appointed laboratories will be established within the hospital to conduct research on the disease. The leper colony will have all the facilities pertaining to an independent community, including police and fire departments, light and water services, cemetery, and postal and telegraph offices.

Government Services

Major Phelan Receives Special Appointment

Major Henry du R. Phelan, U. S. Army, has been appointed representative of the Historical Branch, General Staff, U. S. Army, as liaison officer between the French and American historical sections and attached to the American Embassy, Paris.

What the Government is Doing for the Disabled in War

According to the Federal Board for Vocational Training the status of those who were disabled in the world war is as follows: in tuberculosis sanatoriums, 46,000; in hospitals for treatment, 18,000; in asylums, 19,000; taking vocational training, 27,912, and 5,000 refused government training, making a total of 115,000. In addition there are about 200,000 men who are only slightly disabled.

A Lapel Button for Members of the Officers Reserve Corps

A circular, issued by the War Department, January 17, states that a lapel button for members of the Officers' Reserve Corps has been approved, optional for wear on civilian clothes only. The button is of gold, one-half inch in diameter with the face enameled in the color of the facing of the arm or corps of the service. It has the letters U. S. R. in the center. The button is to be issued by the Quartermaster's Department.

Influenza in Naval Stations

The *Naval Medical Bulletin*, issued to medical officers of the United States Navy, reports mild epidemics of influenza at the Great Lakes Station, and also in the Marine Barracks at Quantico, Va. The type of the disease is reported to be the same as last year, but not so virulent. A few cases have occurred at Gulfport, Miss., and at Charleston, S. C. Special attention is invited to the importance of placing the sick under treatment at once and modifying the routine, if necessary, so that the well may avoid unnecessarily close contact with each other, overexposure to cold and wet and fatigue.

Medical Corps Section of Army Relief

A campaign for a new membership in the Medical Corps Section of the Army Relief Society is under way. The object of the society is the relief and education of widows and orphans of enlisted men of the regular army and it is requested that all members of the Medical Corps or some member of their family become members of the organization

The dues are \$1 a year. Application may be made to Mrs. Merritte W. Ireland, the Wyoming, Washington, D. C., or Mrs. M. A. Delaney, the Northumberland, Washington, D. C.

Government Needs Physicians

The United States Civil Service Commission announces that a number of physicians are needed in the Indian Service, the United States Public Health Service, the Coast and Geodetic Survey and the Panama Canal Service. Both men and women are eligible, salaries of \$200 a month are offered with prospective promotion and higher pay. Information and application blanks will be obtained from the commission at Washington, D. C., or the civil service board at any of the principal cities in the United States.

Care of Discharged Soldiers

Over 10,000 discharged, disabled soldiers were undergoing treatment in Public Health Service hospitals, or under contract with private hospitals, during January, according to tabulated returns. The number of applicants for treatment under the war risk act is constantly increasing, as the men become familiar with the fact that they are entitled to free treatment. The United States Public Health Service is now operating forty-three hospitals for the care of discharged, disabled soldiers, sailors, marines and war nurses, who are beneficiaries of the War Risk Insurance Act.

Army Turns Over Hospital Equipment to Fight Epidemic

The Secretary of War has been permitted to turn over to the State of Kansas emergency hospital equipment of the army to check the present influenza epidemic in that state. The Senate moved with unusual speed on this resolution, which was passed the day it was introduced. Senator Curtis and Governor Allen of Kansas asserted that the Topeka High School has been converted into a temporary hospital and that 150 influenza patients are being treated there. Similar conditions exist in many of the Kansas state institutions. This is the first instance where state government officials have asked for emergency relief from the War Department.

Medical Veterans of the World War

Col. Frederick F. Russell, M. C., U. S. Army, secretary of the Medical Veterans of the World War, states that during January, 143 new members joined, making a total membership of 2,542, divided as follows:

Medical Corps, U. S. Army.....	1,116
Medical Corps, U. S. Navy.....	46
Medical Corps, U. S. P. H. S.....	59
Contract Surgeons, U. S. Army.....	85
Acting Assistant Surgeons, U. S. P. H. S.....	44
Members Local Board.....	512
Members Examiner, Local Board.....	174
Members Medical Advisory Board.....	506

Army Hospitals in Operation

On January 9, fourteen army hospitals were in operation with 14,370 bed patients, distributed as follows:

U. S. General Hospital No. 28, Fort Sheridan, 2,800; Walter Reed General Hospital, Takoma Park, D. C., 1,675; U. S. General Hospital No. 2, Fort McHenry, Md., 1,447; Letterman General Hospital, Presidio, San Francisco, 1,245; U. S. General Hospital No. 41, Fox Hills, N. Y., 1,518; U. S. General Hospital No. 21, Denver, Colo., 1,088; U. S. General Hospital No. 6, Fort McPherson, Ga., 914; U. S. General Hospital No. 19, Otteen, N. C., 887; U. S. General Hospital, Fort Bayard, N. M., 698; Base Hospital, Fort Sam Houston, Texas, 713; U. S. General Hospital No. 31, Carlisle, Pa., 560; U. S. General Hospital No. 43, Hampton, Va., 319; U. S. General Hospital No. 20, Whipple Barracks, Ariz., 351; Army and Navy General Hospital, Hot Springs, Ark., 155.

U. S. General Hospital No. 20, Whipple Barracks, Ariz., and No. 43, Hampton, Va., will be closed February 15, and such patients as require further treatment will be transferred to other hospitals.

Neurosurgical Unit in Richmond

It is announced that Richmond, Va., has been selected as the place of the fourth district, embracing Virginia, Maryland, District of Columbia and West Virginia, in which a neurosurgical unit is to be established to treat and care for veterans of the world war suffering from injuries of

the brain, spinal cord and nerves. Arrangements have been made to give treatments at Memorial Hospital, Richmond, and the Retreat for the Sick. The personnel of the unit includes Drs. Claude C. Coleman, Paul V. Anderson and John H. Baird, all of Richmond; Dr. William F. Mercer, Richmond, will have charge of all cases of diseases of eye, ear, nose and throat; Asst. Surg. Clavel T. Wilfong, U. S. P. H. S., will treat all office cases discharged from hospitals in Richmond, and all cases sent through hospitals in Richmond will be under the care of Dr. William R. Jones, Richmond.

Legislation for Care of Mental and Nervous Diseases in Men of Army and Navy

A bill has been introduced by Congressman Edward J. King, of Illinois, "to provide for the segregation and care of men in the Army and Navy afflicted with mental and nervous diseases." The bill provides for the appointment of a Board of Sanitarium Commissioners to be composed of five medical officers in the Army and Navy. The board is authorized to select and purchase a site and erect a hospital thereon for the care and treatment of soldiers and sailors afflicted with mental or nervous diseases. At present men suffering from these disorders are confined at the Saint Elizabeth Insane Hospital in the District of Columbia and other similar government institutions for the insane. The purpose of this legislation is to care for these men at a separate institution where their maladies may be given special treatment and where the sufferers will not be placed in the distressful environment of an insane hospital, as is now the practice. It is understood that the bill was introduced at the request of the American Legion. Senator McKellar, of Tennessee, has introduced the same bill in the Senate.

The Discharged Soldier's Problem

The United States Public Health Service is making wide advertisement of the channels through which a discharged soldier may receive treatment at the hands of the Public Health Service to which he is entitled as beneficiary of the Bureau of War Risk Insurance. He may obtain treatment through: 1. Application to the examiner of the Public Health Service in the soldier's locality on presentation of an honorable discharge as evidence of his right to such treatment. The examiner will examine him, treat him, and make provision for necessary hospital care and will also instruct him in making out the necessary forms to be forwarded, to the Bureau of War Risk Insurance and to the Federal Board for Vocational Education. 2. Application to the Bureau of War Risk Insurance by letter, requesting examination and treatment. The bureau notifies the district supervisor who in turn notifies the patient to report to an examiner, giving the examiner's name and address and issuing transportation for travel when necessary. 3. Application to the American Red Cross, the American Legion, county or state board of health, or to welfare organizations who will either direct him to the nearest examiner of the service or will take up his case with the district supervisor.

Health Conditions of the Army

For the week ending January 30 the admission rate for disease was considerably greater than for the previous week, because of the rise of the influenza epidemic. Influenza patients are being kept in the hospital until all symptoms of the disease have disappeared and the possibility of pneumonia following has been guarded against. This period is at least ten days after the temperature has become normal. For this reason the noneffective rate of the Army is very high. The increase in the number of new cases of influenza concerns not only the home forces, but also the American forces in Germany and in Siberia.

It is noted that the present epidemic of influenza in the United States is not as severe in type as that which occurred in 1918. For comparison, the figures from Camp Grant, Ill., are cited: This camp had a most pronounced epidemic, both in 1918 and in the present year. At the time of highest incidence in 1918, one person out of every 4.28 contracted influenza, whereas in the present epidemic, one person out of 11.4 contracted the disease. In 1918 one of each 16.86 contracted pneumonia; this year one of 141.61. In the 1918 epidemic, one person of 47.62 died; this year, one of 399.01 died.

The Camphor Scarcity

The embargo placed on camphor by the Japanese government, which seek to make Japan the sole source of supply for the crude gum, has given impetus to the manufacture of synthetic camphor. This scarcity of crude camphor, which is reaching an acute stage and threatens to stop the preparation of pure gum in American laboratories, has caused manufacturers in the United States to make an effort to establish a laboratory for the manufacture of synthetic camphor which would produce sufficient quantities of camphor to supply the needs of their industries. Also at Segni, Italy, a laboratory for the manufacture of synthetic camphor has recently been established, and a similar enterprise is about to be launched in France.

Since oil of turpentine can be secured very cheaply by the distillation of resinous woods, it is easy to produce synthetic camphor at a reasonable price. In all cases in which a hydrocarbon is to be used in the manufacture of synthetic camphor, oil of turpentine proves the most available. It happens that France is a large producer of oil of turpentine, and it is possible to increase still further our pine forests—the seaside pine in the western part of France and the Aleppo pine in the Southeast and in Algeria. The Comité interministériel des plantes médicinales, in collaboration with the Office des matières premières, is engaged at the present time in collecting information on the subject of the manufacture of synthetic camphor, and in the near future it proposes to call a meeting of technicians and manufacturers with a view to taking immediately the necessary steps to assure to France, as soon as possible, its normal supply.

But it is to be hoped that the natural camphor may keep its place alongside the synthetic product, the manufacture of which is furthered by the existing circumstances. In this connection it may be well to mention that the camphor laurel grows naturally in some of our colonies, notably in Tonkin (Indo-China), and also in Algeria, where the camphor produced from the leaves is identical with that produced from the same kind of trees in Japan.

Reorganization of the Municipal Chemical Laboratory

The municipal council of Paris is considering the interesting proposition of reorganizing the municipal chemical laboratory. The purpose of this laboratory when originally founded in 1878 was to protect the public against fraudulent adulteration of wines, but the principal function of the laboratory at this time would be the suppression of frauds in general. The plan is to make of it a center of scientific study.

Opposition to Paid Courses of Medical Instruction

Contrary to the current practice in Germany, where university professors often give paid courses of instruction, this custom has not been accepted in this country and has been at times severely criticized; for example, the paid graduate medical course organized by Dr. de Lapersonne, professor of clinical ophthalmology of the Faculté de médecine de Paris, has recently been quite severely criticized by "A Reader" in the *Journal des Praticiens*:

"I admit that an eminent physician who is known by his writings, his researches, or his skill in teaching, and being duly authorized, may announce paid courses of instruction. The poor man who has no private fortune, as is so often the case, cannot spend his time without compensation. He may not receive the 15,000 francs of a regular professor, which he needs to support himself and family; but that a regular professor of the Faculté de médecine de Paris should require fees of his students surpasses all belief, and we cannot protest too vigorously against such tendencies, which threaten to become general."

Exhibit of French Pharmaceutical Products in Canada

M. Beaubien, Canadian senator, recently paid a visit to the Comité Français des Expositions à l'étranger, and during the course of his visit suggested a plan by which French interests in Canada might be served, namely, by an exhibit of French products. But, as the distances between the cities of Canada are very great, he suggested that the exhibit be put on wheels, explaining that, in a train of eight coaches, samples of all French products, and more particularly, pharmaceutical products, might be exhibited. Two coaches might be placed at the disposal of the representatives of the

exhibitors. This traveling exhibit may be taken through all of Canada, remaining from two days to a week in various cities, according to their importance. Moving pictures would accompany the exhibit.

Preferential Milk Tickets for Prospective Mothers

At the suggestion of Professor Pinard, the prefect of the department of the Seine has sent out instructions to the maires of twenty arrondissements of Paris, relative to supplying prospective mothers with preferential milk tickets. These tickets will be issued on presentation of a certificate, signed by an obstetric nurse of any of the Paris hospitals and setting forth the necessity of a milk diet, the quantity of milk needed daily, and the duration of the regimen.

Tuberculosis in the Regions of France Evacuated by the Germans

Dr. Calmette, assistant director of the Institut Pasteur de Paris, who, in his capacity of director of the Institut Pasteur de Lille, has been conducting an inquiry into the state of the public health of Lille during the years of German occupation, has recently communicated the sad results of his investigation. He thinks the ravages of tuberculosis, both glandular and pulmonary, in the countries of the North were due to the restrictive diet to which the children were subjected during the period of occupation. Tuberculous children who have been sent out into the country or to the seaside have improved remarkably. Calmette recommends that such therapeutic treatment be continued and that all schoolchildren be examined carefully from time to time. He also advises the establishment of antituberculosis dispensaries for adults. Calmette adds that the appeals of Germans in favor of German children who are suffering in great number must not allow us to forget the lamentable consequences of the inhuman conduct the Germans showed, during the long period of occupation, toward our own children.

History of Medicine and Pharmacy

At the last meeting of the Société française d'histoire de la médecine it was decided to hold a congress of the history of medicine and pharmacy at Antwerp, Aug. 7-12, 1920, coincident with the kermess and the celebration of the Olympian games. The principal subjects thus far selected for discussion are: Medical iconography and epigraphy; a chapter from the history of welfare movements in various countries; medical bibliography; monastic and collegial medicine in Belgium, and the mobiliary equipment of apothecaries.

LONDON

Jan. 22, 1920.

The Prevention of Influenza

In view of the possibility of another epidemic of influenza this winter, the ministry of health has been studying the measures to limit its incidence and mortality, and has revised a memorandum previously issued on the subject. The difficulty of securing a continuous record of true influenza has made it impossible to forecast with any confidence the arrival of the next wave. We do not yet know the nature of the virus, and the laboratory has not yet furnished a specific form of treatment or prevention. Pfeiffer's bacillus cannot be regarded as the essential causative organism, but for present purposes is looked on as an important secondary or coincident agent responsible for many of the fatal complications. As infection is conveyed by coughing, sneezing and even loud talking, overcrowding should be avoided. The evidence collected by the ministry shows that acute and temporary overcrowding in trains, cars and places of entertainment is more important than overcrowding in the home. Personal protection includes good ventilation, good food, gargling the throat and douching the nose with 1:5,000 potassium permanganate. Face masks are advised for those attending the sick, but not for the public. As regards vaccines, it is laid down that since we are uncertain of the primary cause, no form of inoculation can be guaranteed to lessen materially the incidence of the disease. Vaccines may, however, lessen the dangers of complications. Drugs are of little avail. When attacked, the patient should take to bed. A standard polyvalent vaccine prepared from strains of Pfeiffer's bacillus, pneumococcus and streptococcus appears to reduce materially the liability to complications and the risk of death. Therefore, it should not be neglected. The bacteriologists of the Medical Research Committee believe that in the previous government vaccine the proportion of Pfeiffer's bacillus was too small, and that better results might follow the use of a vaccine in which this microbe forms the dominant constituent and of which a much larger

dose is given. The ministry has accordingly made arrangements for the preparation of a considerable quantity of prophylactic vaccine made from the new formula. This will be issued in bottles of 25 c.c. each to health officers for distribution on demand, and free of charge to physicians, who will be expected not to charge their patients for the vaccine used. It is further proposed to arrange for the preparation of vaccines in selected localities from the strains of microbes associated with local cases of influenza. The prevention by quarantine of the importation from abroad is regarded as impracticable. Health authorities should distribute information to the public by leaflets, posters, notices and lectures. In Sheffield during the last epidemic a "pool" of unattached physicians was formed with good results, their services being placed at the disposal of physicians as required. In the larger areas, part of such a pool might be formed from the health authorities' own staffs.

Increased Remuneration for Panel Physicians

The increase in the cost of living in this country since the war has amounted to more than 100 per cent. and has led to demands for increased wages in practically every calling. As reported in *THE JOURNAL*, physicians have increased their fees by 50 per cent. The panel physicians demanded from the government an increase of the capitation fee from \$2 to \$3.25. A deputation of the Insurance Acts Committee of the British Medical Association was received on the subject by the minister of health, Dr. Addison. He offered to seek the authority of Parliament to pay an increased fee of \$2.75, with a mileage fund of \$1,500,000 for rural physicians. The deputation said that it would feel bound to its constituents not to accept this, but it was empowered to ask for arbitration, which it did. After discussion, the minister announced that the government would accede to this request. The arbitrators' award will operate from April 1, the government agreeing to pay in the meantime a capitation fee of \$2.75. The government reserved its freedom to institute at a subsequent date any inquiry that might be thought desirable, in the light of the award and the cost of its working, into the question whether service as good or better could be secured with the same or less expenditure of money, under some other system.

As a result, no doubt, of this increase the government has decided to increase by 6 cents the weekly contributions paid, of which 4 cents will fall on the employer and 2 cents on the employed person. The rate of sickness benefit is to be increased to \$3.75 a week in the case of men and \$3 in the case of women. Maternity benefit is to be increased from \$7.50 to \$10. Sanatorium benefit is to be removed from the acts, the treatment (other than domiciliary) of tuberculosis, among both the insured and the uninsured, being recognized as falling within the province of the local authorities. A state system of medical referees is to be established, toward which the societies will make a small contribution by way of payment for each case referred.

New Hospital for Tropical Diseases in London

The study of tropical diseases in London originated in the Seamen's Hospital at Greenwich, where sailors suffering from tropical diseases are received from all parts of the world. A branch hospital for tropical diseases, containing thirty beds, was established in the East End of London, at the Albert Docks. Among the patients are Europeans of all nations, Asiatics, Africans, West Indians and natives of British and other colonies. A laboratory was built in connection with the hospital, and more than 2,000 physicians were trained in the study of tropical diseases. But the accommodation became inadequate. In the "University Quarter" of London, at Endsleigh Gardens, a hospital established for officers during the war was therefore secured. In this much more central and accessible position the several departments of the London School of Tropical Medicine will be housed. The riverside wards will be retained for patients who, for various reasons, should not be taken to the new hospital. But hundreds of cases of tropical disease in the chronic stage will be available for study in the latter.

Death of Sir Thomas Frazer

Sir Thomas Frazer, M.D., F.R.S., emeritus professor of materia medica and clinical medicine in the University of Edinburgh, one of the most distinguished investigators of his time, who did much in laying the foundations of modern pharmacology and therapeutics, has passed away at the age of 79. Born in Calcutta of Scotch parentage, he was educated in Edinburgh. On graduation he obtained a gold medal for his thesis on the action and uses of Calabar bean

(*Physostigma venenosum*). He was appointed assistant to the celebrated Sir Robert Christison in the materia medica department of the University of Edinburgh and, like him, he became a great authority on poisons. Among his earlier papers, which have become classical, were "The Antagonism Between the Actions of Physostigma and Atropia," and "The Kombé Arrow Poison" (*Strophanthus hispidus*). On the resignation of Sir Robert Christison in 1877, he was appointed professor of materia medica in the University of Edinburgh. He was also appointed physician to the Royal Infirmary, and as a clinician attained the first rank. In conjunction with Prof. Crum Brown, he made an important investigation into the chemical constitution and physiologic action of poisons, for which the Royal Society of Edinburgh awarded them a prize. It was mainly through his investigations that strophanthus came into use in therapeutics. Some of his best known work was on snake poison. His original observations, made individually or in association with Major Elliot, continued the investigations of Lauder Brunton and Joseph Fayrer on cobra poisoning. Much of our knowledge of the effect on cardiac action of cobra venom is due to his work. When, in 1894, Calmette published his researches into the immunity against snake venom that followed repeated injections of small doses of rattlesnake poison, Frazer, who had already gone over the same ground, gave valuable confirmation to Calmette's work, as well as further points as to the nature of the protective action of the antitoxic serum. Other original work of the first importance emanating from him was on the salicyl compounds in acute rheumatism, the nitrites in the dyspnea of asthma and bronchitis, bone marrow in pernicious anemia, opium, morphin and codein in diabetes, and potassium bichromate in gastric affections. He was one of the first, if not the first, to teach the expression of dosage in terms of body weight and to analyze pharmacologic action into its component parts. All his work was characterized by accuracy and thoroughness. In 1894 he delivered the graduation address at the University of Edinburgh in which he uttered a warning that has been needed ever since and is still needed: He pointed out that recent advances in organic chemistry had led to the discovery of a host of complex substances with possible pharmacologic actions which afforded a great opportunity to charlatanism. He considered that physicians as well as commercial chemists were advocating for all sorts of disease the employment of drugs to which no proper trial could be given. The determination of the physiologic action of any substance might require at least six months' study by a skilled investigator. Like many of the leaders of the profession, he suffered badly in the war. He lost one son on submarine service, and another, as well as a son-in-law, in France. One of his sons is a well-known New York physician and is at present with the American army on the Rhine.

Marriages

DWIGHT CHASE SIGWORTH, Lieut., M. C., U. S. Army, Stanton, Neb., on duty at Alcatraz Barracks, Calif., to Miss Irene L. Cratty of Elgin, Neb., at Long Beach, Calif., February 14.

HENRY BLOODGETT MCINRYRE, Lieut.-Col., M. C., U. S. Army, New York City, on duty at Fort McHenry, to Miss Gladys E. Miller at Mamaroneck, N. Y., January 31.

EDWARD FRANKLIN YOUNGER, Lynchburg, Va., to Miss Bessie Mason of Campbell County, Va., in Washington, D. C., December 15.

THOMAS WISTER EDMUNDS, Danville, Va., to Mrs. Sallie Davis Penn of Reidsville, N. C., in Baltimore, December 20.

CLARENCE WALTER ADAMS, Visalia, Calif., to Miss Marie Genevieve Rogers of Spokane, Wash., December 15.

CHARLES LYNDON OUTLAND, Tarboro, N. C., to Miss Alice Louise Sadler of Richmond, January 21.

HARRY EMMICK LEE, Detroit, to Miss Jamie Florence Greenlee of Studley, Va., December 31.

DR. BENJAMIN F. DAVIS, Chicago, to Miss Marie Lucille Brickson, Stoughton, Wis., February 7.

CLARENDON RUTHERFORD to Miss Ella Williams McCauley, both of Chicago, February 4.

HARRY S. BERMAN, Detroit, to Miss Caroline Block of Richmond, December 23.

MILO KIRK MILLER to Miss Freda Anita Stracke, both of Chicago, January 10.

Deaths

Elmer Ernest Southard * Cambridge, Mass.; Harvard University Medical School, 1901; aged 43; chairman of the Section on Nervous and Mental Diseases of the American Medical Association; died in New York City, February 9, after two days' illness from pneumonia. He was born in Boston and was graduated in arts and in medicine by Harvard University. He later studied at Senckenberg Institute, Frankfurt on the Main, and in the University of Heidelberg. On his return to the United States he became instructor in neuropathology in his alma mater; later assistant professor, and since 1909 Bullard professor of neuropathology. He was assistant visiting pathologist to the Boston City Hospital in 1904 and 1905; assistant physician and pathologist of the Danvers (Mass.) State Hospital from 1906 to 1909; pathologist of the Massachusetts Commission on Mental Diseases in 1909, and director of the Boston Psychopathic Hospital since 1912. He was a director of the Eugenic Record Office, Cold Spring Harbor, N. Y.; a member of the board of scientific directors of the Bedford Hills Laboratory, Bureau of Social Hygiene, New York; a director of the Massachusetts State Psychiatric Institute, and member of the editorial board of the *Archives of Neurology and Psychiatry*. During the war Dr. Southard was director of the U. S. Army Neuropsychiatric Training School, Boston unit, and major in the Chemical Warfare Service. He had devoted particular attention to the pathology of the brain and nervous system in dementia praecox, and published important original investigations on this subject. He also advanced an original classification of the psychoses which had aroused considerable interest. His most recent publication is a large volume on shell-shock and other neuropsychiatric problems, an epitome of war neurology. In his death the medical profession loses a specialist of broad vision, a clinician who was preeminently a neuropathologist with broad training and insight into the problems of general medicine.

Sir James Alexander Grant, K.C.M.G., one of the most distinguished physicians of Canada; died, February 6, at his home in Ottawa, aged 89. He was born in Inverness, Scotland, Aug. 11, 1831, was graduated from McGill University in 1854, and obtained the degrees of M.R.C.P., M.R.C.S. (Eng.) and in 1864 the F.R.C.S. (Edin.). A year before his graduation he passed the examination of the College of Physicians and Surgeons of Quebec, and after graduation located in Ottawa. He was a member of the Provincial Medical Council from 1866 to 1869, and its president in 1868-1869. He was a member of parliament from the council of Russell in 1867, and later from Ottawa City, serving altogether fourteen years. He was made president of the Canada Medical Association in 1874; president of the Royal Society of Canada in 1903; vice president of the International Medical Congress in 1887; was president of the General Hospital, Ottawa, and chief of staff for twenty-five years. In 1887 he was made Knight Commander of Sts. Michael and George, and in 1910 was given the freedom of the city of Inverness. He was an active and honorary member of many scientific societies, and of late years had devoted much of his time to geology.

John Abner Mead, Rutland, Vt.; College of Physicians and Surgeons in the City of New York, 1868; aged 78; a veteran of the Civil War; for several years assistant physician at the Insane Hospital, Flatbush, L. I.; surgeon-general of Vermont in 1878 and 1879; first mayor of Rutland; a member of the state senate in 1892 and of the house of representatives in 1906; lieutenant-governor of Vermont in 1908-1909, and governor from 1910 to 1912; died, January 12, from pleuropneumonia.

Emil Augustus Herig, Saginaw, Mich.; University of Berlin, Germany, 1866; aged 79; formerly president of the board of health, health officer and city physician of Saginaw; coroner of Saginaw County; chief of staff of the Bliss Hospital, Saginaw, and attending physician to the Saginaw General Hospital; once president of the Saginaw Valley Medical College; a veteran of the war between Prussia and Austria in 1866; died, January 21.

Robert William Carter, Montclair, N. J.; College of Physicians and Surgeons in the City of New York, 1904; aged 44; who went to the Philippines as a missionary of the Presbyterian Board at Dumaguete Maasin and Albay; was invalided

home, ill with tropical sprue in 1913; returned to Dumaguete in 1917, and two years later was transferred home; died in the Presbyterian Hospital, New York City, November 21, from sprue.

Julius Stimpson Clark, Melrose, Mass.; Georgetown University, Washington, D. C., 1869; aged 81; a veteran of the Civil War; a member of the Massachusetts Medical Society, and for seven years president of the Middlesex District Medical Society; from 1870 to 1878 health officer, city physician and police surgeon of New Orleans; president of the medical board of the Melrose Hospital; died, January 20, from pneumonia.

James Jefferson Johnson * Braggs, Okla.; Memphis (Tenn.) Hospital Medical College, 1897; aged 43; a specialist on diseases of the eye, ear, nose and throat; who entered the Army in 1913, and was discharged as captain, M. R. C., July 10, 1919, and was then attached to the American Red Cross Commission to Siberia; died in Siberia, December 13, from typhus fever, and was buried at Irkutsk.

Frederick James Bowles * New York City; University of the City of New York, 1884; aged 67; a member of the American Academy of Ophthalmology and Oto-Laryngology, and the New York Academy of Medicine; ophthalmologist, otologist and laryngologist to the Bloomingdale clinic; died in the Post-Graduate Hospital, New York City, January 28, from pneumonia.

William Lewis West, Indianapolis; Miami Medical College, Cincinnati, 1876; also a druggist; cashier and later president of the First National Bank of Oakland City, Ind.; president of the Farmers and Merchants National Bank, Fort Branch, Ind., and the Citizen's Bank and Trust Company of Princeton, Ind.; died, January 2, from heart disease.

R. K. Prewitt, Ackerman, Miss.; Kentucky School of Medicine, Louisville, 1882; aged 77; once president of the Choctaw County (Miss.) Medical Society and local surgeon for the Mobile, Jackson and Arkansas City Railroad; a Confederate veteran; representative in the legislature from Choctaw County in 1896; died, January 22.

Francis B. Nofsinger, Kansas City, Mo.; University of Nashville, Tenn., 1864; aged 82; surgeon in the United States Navy during the Civil War; who established the first packing house in Kansas City in 1859; postmaster from 1889 to 1893; county assessor and president of the city council; died, January 6, from cerebral hemorrhage.

Edward Grant Birge, Iowa City; Johns Hopkins University, Baltimore, 1907; aged 31; formerly instructor in the department of preventive medicine and hygiene in Harvard University Medical School, and later state epidemiologist of Iowa; captain, M. R. C., U. S. Army, and discharged, Aug. 10, 1919; died, February 4, from pneumonia.

Francis Alonzo Bailey, Hillsboro, Ore.; Willamette University, Salem, Ore., 1870; aged 80; a medical cadet in the Confederate Service during the Civil War; twice president of the Oregon State Medical Association; for several terms mayor of Hillsboro and a member of the city council; died, January 23, from pneumonia.

Edward William Spragge, Toronto; M.R.C.S. (Eng.), L.R.C.P. (Edin.), 1868; aged 76; also a licentiate of the Ontario College of Physicians and Surgeons in 1869; for than forty-seven years medical officer of the Toronto police force, and surgeon to the Canadian Pacific Railway Company; died, December 31.

Parker Lloyd Berge, Brainerd, Minn.; University of Minnesota, Minneapolis, 1913; aged 31; a member of the Minnesota State Medical Association; who as a lieutenant, M. C., U. S. Army, was attached to the Aviation Corps for two years, and was discharged, July 7, 1919; died, January 22, from heart disease.

James Albert Rutledge * Woodmen, Colo.; Rush Medical College, 1866; aged 58; formerly a practitioner of Elgin, Ill.; medical director and superintendent of the Modern Woodmen of America Sanatorium since 1911; a specialist in tuberculosis; died in a hospital in San Francisco, February 3, from influenza.

Tucker Henderson Frazer * Mobile, Ala.; University of Alabama, Mobile, 1888; aged 60; dean and professor of obstetrics in his alma mater; head of the American Red Cross in Mobile during the world war; died in the Southern Infirmary, Mobile, January 26, four days after an operation for appendicitis.

James Elias Seay, Birmingham, Ala.; University and Bellevue Hospital Medical College, New York City, 1899; aged 41; a member of the Medical Association of the State

* Indicates "Fellow" of the American Medical Association.

of Alabama; surgeon to the Birmingham Southern Railroad; died, January 26, from cerebral hemorrhage.

Abraham Feldman, Hammonton, Calif.; College of Physicians and Surgeons, Los Angeles, 1916; aged 30; a member of the Medical Society of the State of California; lieutenant, U. S. N. R. F., and relieved from active duty, July 11, 1919; died, January 20, from pneumonia.

Theodore H. Swayne, Chihuahua, Mexico; Northwestern University Medical School, Chicago, 1895; aged 59; also a graduate of the Faculty of Mexico Medical School; for many years a practitioner of Chihuahua and local railway surgeon; died, January 9, from pneumonia.

George Victor Genzmer, Verona, N. J.; Albany (N. Y.) Medical College, 1913; aged 28; assistant surgeon, lieutenant, U. S. Navy, and on duty for two years at Pelham Bay Hospital, and relieved from active duty, Sept. 4, 1919; died, January 30, from pneumonia.

Charles Edward Treble, Toronto, Ont.; College of Physicians and Surgeons, Toronto, 1901; aged 43; in charge of the roentgen-ray department of the Wellesley Hospital; while making his rounds in Grace Hospital, October 29, died suddenly from heart disease.

Hudgins S. Ellis, Memphis, Tenn.; College of Physicians and Surgeons, Memphis, 1911; aged 36; a member of the Tennessee State Medical Association; died suddenly in St. Joseph's Hospital, Memphis, January 25, from acute dilatation of the heart.

Mary Frye Barry, Washington, D. C.; Northwestern University Woman's Medical School, Chicago, 1887; aged 60; for ten years a practitioner of Colorado, and once a member of the state legislature; died in Colorado Springs, Colo., December 8.

Harry Stoddard Clever, Tuscarawas, Ohio; University of Pittsburgh, 1897; aged 46; a member of the Ohio State Medical Association; health officer of Tuscarawas; died in Grant Hospital, Columbus, Ohio, January 20, from heart disease.

Charles O. Warner, Warsaw, Ill.; Washington University, St. Louis, 1863; aged 89; assistant surgeon of volunteers in the Army during the Civil War; for many years a member of the local school board; died, January 15, from bronchial asthma.

George R. Green, Muncie, Ind.; Medical College of Indiana, Indianapolis, 1878; aged 68; a member of the Indiana State Medical Association, and lecturer on history of medicine in the Indiana Medical College; died, January 24, from pneumonia.

Riley J. Drew, Alma Center, Wis.; Medical College of Indiana, Indianapolis, 1904; aged 45; a member of the State Medical Society of Wisconsin; died, December 28, in Sacred Heart Hospital, Eau Claire, Wis., from bronchial pneumonia.

Joseph Aurelius Young, Caldwell, Idaho; University of Illinois, Chicago, 1903; aged 41; was accidentally drowned, January 20, when his automobile slid off the ferry platform at Froman's ferry into the Snake River.

May Cushman Rice ☉ Chicago; Northwestern University Woman's Medical School, Chicago, 1896; aged 56; a specialist in roentgenology and electrotherapeutics; died, February 4, from pneumonia following influenza.

Sylvanus Joy, Tillsonburg, Ont.; University of the City of New York, 1854; Queens University, Kingston, Ont., 1857; aged 85; for forty-five years local surgeon for the Grand Trunk system; died, October 31.

Robert Kearns ☉ Middletown, N. Y.; College of Physicians and Surgeons in the City of New York, 1888; aged 54; a specialist in diseases of the ear, nose and throat; died, January 21, from septicemia.

Maurice Henry Miesse, Circleville, Ohio; College of Physicians and Surgeons in the City of New York, 1868; aged 76; a veteran of the Civil War; died, January 21, from cerebral hemorrhage.

John Eugene English, Baraboo, Wis.; Rush Medical College, 1883; aged 68; for thirty-seven years district surgeon for the Chicago and Northwestern system; died, January 24, from myocarditis.

Frank A. Sabin, Anna, Ill.; Berkshire Medical College, Pittsfield, Mass., 1861; aged 84; an honorary member of the Illinois State Medical Society; died, January 26, from arteriosclerosis.

Robert Addison Stevenson, Toronto; McGill University, Montreal, 1871; aged 73; chairman of the staff and chief of

the medical service of Grace Hospital, Toronto; died, November 12.

Thomas T. Zerbe, Schaefferstown, Pa.; University of Pennsylvania, Philadelphia, 1869; aged 74; for two terms a member of the state legislature; died, January 26, from cerebral hemorrhage.

Thomas Kelly Proctor, Sulphur Springs, Texas; University of Louisville, Ky., 1895; aged 60; a member of the State Medical Association of Texas; died last month, from carcinoma.

George Henry Albers, Cincinnati; Miami Medical College, Cincinnati, 1887; aged 57; a member of the Ohio State Medical Association; died, January 19, from cerebral hemorrhage.

John Schulze, Racine, Wis.; Bennett Eclectic Medical College, Chicago, 1894; aged 68; for more than half a century a druggist of Racine; died, January 26, from diabetes.

Edward E. Engel, St. Louis; Washington University, St. Louis, 1877; aged 66; for thirty-two years a practitioner of Prairietown, Ill.; died, January 21, from cerebral hemorrhage.

Christopher Columbus Lathers, Lieut., M. R. C., U. S. Army, Washington, D. C.; Howard University, Washington, D. C., 1914; aged 40; died, January 23, from pneumonia.

John M. Wiltshire ☉ Chillicothe, Ohio; Starling Medical College, Columbus, Ohio, 1865; aged 85; a veteran of the Civil War; died, January 17, from valvular heart disease.

Victor Knapp, Ferdinand, Ind.; Medical College of Ohio, Cincinnati, 1881; aged 62; a member of the Indiana State Medical Association; died, January 10, from uremia.

Alexander Crawford ☉ Mount Vernon, Iowa; Rush Medical College, 1883; aged 61; formerly health officer of Mount Vernon; died, January 10, from angina pectoris.

John M. Littler, Fortville, Ind., and Indianapolis; Kentucky School of Medicine, Louisville, 1876; aged 72; died in St. John's Hospital, Anderson, Ind., January 19.

Orson S. Parker, Aurora, Ill.; Tulane University, New Orleans, 1892; aged 52; a member of the Illinois State Medical Society; died, February 5, from pneumonia.

Noah J. LaRose, Zion City, Ill.; Eclectic Medical Institute, Cincinnati, 1885; aged 68; health officer of Zion City since 1902; died, January 18, from influenza.

Franklin Newton Hudson, Gadsden, Ala.; University of Nashville, Tenn., 1874; aged 71; died at the home of his daughter in Birmingham, Ala., January 20.

Joseph A. Liddell, Cedartown, Ga.; Medical College of Georgia, Augusta, 1879; aged 65; a member of the Medical Association of Georgia; died, January 1.

Henry Harlan Townshend ☉ Hedgesville, Mont.; John A. Creighton Medical College, Omaha, 1896; aged 51; died, January 10, from cerebral hemorrhage.

Edward Burns Hughes, Canton, Ill. (license, Illinois, 1878); aged 78; died at the home of his sister in Ipava, Ill., January 23, from senile debility.

Charles Buchanan Young, Lynchburg, Va.; Hahnemann Medical College, Philadelphia, 1881; aged 68; died, January 13, from cerebral hemorrhage.

Wallace G. Bobb ☉ Philadelphia; University of Pennsylvania, Philadelphia, 1880; aged 59; died, January 25, from pancreatitis and septicemia.

Alexander Duff Stevens, Dunham, Que.; McGill University, Montreal, 1857; died in the General Hospital, Sweetburg, Que., November 22.

Charles H. Wells, Philadelphia; Hahnemann Medical College, Philadelphia, 1891; aged 55; also a dentist; died, January 19, from pneumonia.

Charles Franklin Banta ☉ Eureka, Ill.; Bellevue Hospital Medical College, 1884; aged 63; died in the Methodist Hospital, Peoria, January 10.

Ralph Erskine Moffatt ☉ Harrisburg, Pa.; University of Pennsylvania, 1904; aged 43; died, January 26, in Cumberland, Md., from uremia.

Joseph Harris Cowell, Saginaw, Mich.; University of Michigan, Ann Arbor, 1871; aged 72; a veteran of the Civil War; died, January 18.

J. L. Underwood Cochran, Atlantic City, N. J.; Louisville (Ky.) Medical College, 1892; aged 47; died, December 24, from acute nephritis.

Alfred T. Evans, Rayville, La.; University of Alabama, Mobile, 1873; aged 71; died in Providence Hospital, El Paso, Texas, December 31.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

"AUTO-HEMIC SERUM"

A Cure for Laziness, Ugliness, Frigidity and Many Other Things

The following letters are typical of many that have been received asking for information regarding Dr. L. D. Rogers and his "Auto-Hemic Serum." This from a physician in New York state:

"Can you give me any information in reference to Dr. Rogers of Chicago, Ill., who has an Auto-Hemic Institute?"

And this from Kansas:

"Just received a letter from a Dr. L. D. Rogers, 2812 North Clark St., who is anxious to sell me a course in 'Auto-Hemic Therapy.' Would you kindly inform me what he has to sell? He did not tell me what it consisted of; am inclined to believe it is a rank fake. Kindly let me know what THE JOURNAL thinks about it. Just what is it? In the letter they claim that it is practically a panacea for every blood disease."

This from Maine:

"What is Auto-Hemic Therapy? I have a handsome red and yellow circular from the Ideal Life Extension Press, 2812 North Clark St., Chicago, soliciting subscriptions to their publication, offering as a bonus this book, 'Auto-Hemic Therapy' by L. D. Rogers, A.M., M.D., LL.D., Chicago, and membership in the American Medical Union."

THE NATIONAL MEDICAL UNIVERSITY

In order better to appreciate the probable scientific status of the "Auto-Hemic Serum," it is well briefly to sketch some of the previous activities of its discoverer, Dr. L. D. Rogers. For many years Rogers was the head and chief owner of the National Medical University of Chicago, a low-grade school of the "sun-down" variety. The "university" is now out of existence and for some time before it went out of existence was not recognized either by the board of health of the state in which it operated or by the boards of the majority of the other states in the Union. The report of the Carnegie Foundation on medical education had this to say about the laboratory facilities of Rogers' school:

"The school occupies a badly lighted building, containing nothing that can be dignified by the name of equipment. There has been no dissecting thus far (October to the middle of April, 1909), anatomy being didactically taught. Persistent inquiry for the 'dissecting-room' was, however, finally rewarded by the sight of a dirty, unused, and almost inaccessible room containing a putrid corpse, several of the members of which had been hacked off. There is a large room called the chemical laboratory, its equipment 'locked up,' the tables spotless. 'About ten' oil-immersion microscopes are claimed—also 'locked up in the storeroom.' There is not even a pretense of anything else. Classes in session were all taking dictation."

Dr. Rogers is, or was, if he is not still, "Permanent Secretary" of the "National Association of Panpathic Physicians"—whatever that is. In fact, one of Dr. Rogers' specialties seems to be the founding of quasi-medical organizations—organizations, apparently, which may prove useful in the promulgation of such projects as he may, at the time, be interested in. A few years ago Rogers was exploiting a "cancer serum" and, *præsto*, the "American Cancer Research Society" came into being, L. D. Rogers, president. Soon thereafter certain members of the profession were circularized urging them to purchase shares in the "Cancer Research Laboratory and Hospital," par value \$10. Apparently, the profession did not invest.

A few years ago, also, L. D. Rogers' name appeared on the "Faculty" list of the "American Post-Graduate

School," a concern which granted—on the mail-order plan—a long line of sonorous degrees and an equally complete line of ornate diplomas.

THE JAPANESE CONSUMPTION CURE

Then, in 1915, there appeared in the classified columns of certain newspapers the following advertisement:

TUBERCULOSIS—New Japanese treatment: to prove merits and give discovery quick publicity will send 10 days' treatment free. DR. ROGERS, 346 Surf St., Chicago.

So far as we have been able to learn, Rogers, for some unexplained reason, did not call into existence out of the vasty deep a "Japanese-American Tuberculosis Research Society." This consumption cure apparently died of inanition.

Then came the "Auto-Hemic Serum" with its inevitable sequel, the "National Society of Auto-Hemic Practitioners." Another adjunct to the serum exploitation is the *North American Journal of Homeopathy*, the official organ of the "Auto-Hemic Practitioners" and of the "American Medical Union" and possibly of some other "societies"—but not representative of homeopathy!

WHAT IS AUTO-HEMIC THERAPY?

What is this new therapy? According to a very lurid poster it is described as "The Missing Link in Medicine"—possibly referring to the ease with which one may make monkeys of certain physicians. More specifically, although still vaguely, we learn:

"It consists in giving the patient a solution made by attenuating, hemolizing, incubating and potentizing a few drops of his or her own blood, and administering it according to a refined technic developed by the author."

Elsewhere it is said to consist:

"... in taking five drops (or some multiple of five) of blood from a vein and putting it into nineteen times as much sterilized, distilled water, and incubating it at fever temperature for twenty-four hours, and then making further dilutions according to the needs of the case, as can be determined only by a physician skilled in its use."

Neither of these statements, of course, describes the "refined technic" of those "skilled in its use," but those who are interested can, by sending Dr. L. D. Rogers, "One Hundred Dollars cash-in-advance" get a mail-order course in this new marvel.

But if it is rather expensive to learn just how to use "Auto-Hemic Serum" it does not cost so much to learn what the "serum" will do. Rogers has written a book on the subject, "Auto-Hemic Therapy," which is used as a premium for subscriptions to the *North American Journal of Homeopathy*, price "\$5.00 per year, payable in advance." In the book Dr. Rogers modestly assures his readers that he considers his discovery more important than that of Alex. Carrel, winner of a Nobel Prize.

A CURE FOR LAZINESS

One of the chief virtues claimed for this serum is that of developing in the patient who takes it an unbounded energy that, apparently, makes him want to work himself to death. In some sensational articles that have appeared in Sunday editions of newspapers on Rogers' serum, the stuff has been described as "Lazy Serum." One of the first cases described in the Rogers book is that of a young waiter, "a good-for-nothing lazy fellow who would not work and would not pay for medical services" and who was turned over to Dr. Rogers' free clinic. He was given the serum on Thursday and was told to report Saturday. He did not return until Monday, his excuse being that "he worked all day Saturday until midnight and all day Sunday and felt as if he could work all day and all night without rest." The "case report" ends:

"... finally remarking, 'I feel like a bird' he flew out of the classroom and we never saw him again."

HOUSEWIVES TAKE NOTICE

The next case described is that of a servant girl who had not worked for a year; within a week after taking the "Auto-Hemic Serum" "she voluntarily beat carpets till she

blistered her hands." Then there was the rooming house keeper who had spent more than half of each day in bed. After an "Auto-Hemic" injection she "discharged her maid and janitor . . . and did all the work of her twelve room house herself, beating rugs, firing furnace and carrying out ashes besides doing some of the laundry." "Case No. 7176" is interesting: a man, generally considered the laziest person in his community and with a habit of "drinking thirty whiskies a day," took "Auto-Hemic Serum." He stopped drinking, shaved himself and changed from "a 'bum' to that of a sober, clean, wholesome, bright and honest workman." Then there was the case of the "lady physician" who "took the serum one evening and the next evening reported that she had had the 'giggles' all day"; also she became "more magnetic." More remarkable still was the case of the young woman clerk in a retail store who, after taking the serum "astonished her employer by volunteering to work over time." In the chapter dealing with "Ills Peculiar to Women" Dr. Rogers details the moving story of a man to whom the "serum" was given and who reported that "about the third twenty-four hours after taking it his bowels moved forty times"—nevertheless, "he felt no exhaustion."

In all phases of human activity the serum seems to work wonders. "The cases are numerous in which the frigidity of both sexes have [*sic*] melted after Auto-Hemic treatment." A young married woman with a morbid dislike for her husband took the serum and within a week "became normal." The discoverer suggests that in some cases there is no doubt that this serum "would prevent divorce." A forty-year-old woman who could not endure to wear any waists but white or black was able, it seems, after taking the serum to tolerate a veritable Jacob's coat.

Is, then, "Auto-Hemic Serum" good for everything? Let Dr. Rogers answer:

"Briefly stated, without any great exaggeration, this new modified serum treatment is good for anything that is the matter, with you, provided the cause is not organic, mechanical or bacterial."

One infers that in the inorganic, mental, spiritual and non-bacterial spheres the stuff is supreme. But it has its limitations. For instance, Dr. Rogers states that he once had "a very troublesome cough which lasted several weeks, but did not yield to this serum." Reaching the conclusion that some other treatment was necessary "he had the bones of his neck 'adjusted' and got immediate relief."

AS A COMPLEXION BEAUTIFIER

The serum "cannot be made up by the barrel and sold at wholesale or retail":

"If it could be bottled and stored and sold at retail like a patent medicine, the demand for it as a complexion beautifier alone would net the proprietor millions. More than one person a few days after taking the treatment has been wrongly accused of painting."

Should any of THE JOURNAL readers decide to take the \$100 mail-order course in "Auto-Hemic Therapy" he should realize that even after he has done so there are certain restrictions in the practice of this "therapy." In no case must he administer "a course of Auto-Hemic Treatment" for "less than \$100, paid in advance." The only exceptions to this rule are "cases of absolute charity, expectant mothers and to persons positively unable to pay that amount." Furthermore, Dr. Rogers says that for the reputation of his method, as well as for the good of all concerned, "I insist that the entire fee be paid in advance and that the course extend over a period of one year whether the patient needs few or many treatments."

DOLLARS AND CENTS

For those who do not wish to take the mail-order course Rogers offers to prepare individual specimens of the "serum" from blood that is sent to him by the physician. The cost of this "serum" is \$5.00, "in advance," of course.

Still emphasizing the commercial side, "Auto-Hemic Therapy" is especially recommended to "the general practitioner growing old and the physician who is ambitious to build up a creditable and lucrative office practice" because "the health of four people out of five (old or young, whether they consider themselves sick or well) taken at random can

be improved by this method of treatment"! An Ohio physician was said to have doubled his \$3,000 practice in two years after starting the "Auto-Hemic" method. A Virginia physician is alleged to have "increased his income \$10,000 a year." A Pennsylvania physician, urged by Rogers to send \$150.00 for the mail-order course, was assured that this "is merely a nominal amount, as most of the doctors have been able to get this amount back the first month."

But enough. The story, were it not for the tragic element that forms the background, would be amusing. But it is tragic!

Correspondence

"UNIVERSAL MILITARY TRAINING"

To the Editor:—Your commendation of the provisions for compulsory universal military training in the Wadsworth army bill in your editorial published in THE JOURNAL, January 31, I understand to be an endorsement of militarism. It does not seem possible that any one can avoid this conclusion who is familiar with the history and growth of this institution.

Before the war, in Europe, militarism was a subject much discussed; but here in the United States it received little attention because it did not concern us at that time and very few believed that it would ever be seriously proposed as the policy of our country. Now it has become one of the most important questions of our national life. In a few days the question may be decided by Congress, and your editorial may have important influence in determining the decision. I suppose we may reasonably assume that this was the purpose of the editorial.

I do not now propose to present objections to militarism, but I would like to call your attention to the fact that the advisability of introducing this institution into our national system is by no means admitted by all. On the contrary, this proposal is debated by the most serious students as an exceedingly important problem. I question your right to commit the Association to its endorsement. [The House of Delegates of the American Medical Association is the only body which can commit the Association to any policy; THE JOURNAL does not presume, pretend or intend to arrogate this right to itself.—Ed.]

You may claim that military training has some other purpose than the building up of a military system. You may contend that the four months' period of training, which you say is quite too short, is desirable for other reasons than because it furnishes the basis of a very large and trained American army. If you mean that military training is desirable for some other reason than this and for reasons that are so good that they might overbalance the dangers of militarism, it would seem proper that you indicate in some way why you commend it.

If your editorial were in a lay publication that made no claims to authority on questions of health and physical training, one might assume that you had in mind the value of military training for physical development. Your knowledge of the unfavorable reception heretofore accorded by Congress to public health measures must raise a doubt in your mind concerning the conversion of this body implied in its willingness to appropriate from 600 to 1,200 millions of dollars for a health measure. Moreover, it must seem strange that the military forces of the country have suddenly become so intensely interested in a health measure.

This argument for military training is so generally discredited by experts in physical education, and its honesty is so thoroughly impeached by the fact that the proposed compulsory training exempts those who most need it, that is, those least well developed physically as well as all girls, that it is not possible to assume that this senile and badly discredited reason is what you had in mind.

I hope you will inform your readers why you as representative of the American medical profession endorse this measure that some undoubtedly regard as vitally wrong.

C. S. BACON, M.D., Chicago.

"EFFICIENT HOSPITALS": SUCCESS OF PRIVATE ROOM PLAN AT TEMPLE, TEXAS

To the Editor:—I have read with interest the article by Bacon on "The Efficient Hospital" (THE JOURNAL, Jan. 10, 1920, p. 123). It may be of some interest to your readers to know that the plan suggested is not only feasible, but has been in operation for many years at the King's Daughters' Hospital, Temple, Texas. Some years ago the staff of this hospital realized that the patients, especially the operative cases, would be better in private rooms than in the wards. Something like twelve years ago we abandoned the ward system entirely, and since then each patient, charity or otherwise, has had a private room, and it is seldom that the nurse in attendance knows whether the patient is a pay or a charity patient. So far as I know, this is the only hospital that gives charity patients private rooms. The rates of our rooms now run from \$2 to \$6 a day. Last year there were comparatively few calls for charity outright, but all of these were met with service in such rooms as were available at the time. It goes without saying that we do not put the charity patients in the most expensive rooms.

We have had to work practically without donation, except what little the physicians themselves have contributed, and no endowment. We now have a hospital of seventy-five beds. Of course there is some debt for buildings. Most of the buildings are of modern fire-proof construction. I merely mention this to show that the plan can be worked without wards, and charity taken care of, if the administration is thoroughly efficient. A rather stringent rule, that has been lived up to with practically no friction, is that the hospital bill shall be paid before the attending physician or surgeon can receive any pay.

Instead of having four wings, as suggested by Bacon, we have an L-shaped building with arms of about equal length, with the elevator and dumb-waiter at the angle. It is so arranged that no patient is as much as 100 feet from the distributing center. We have long since adopted the plan as suggested by Bacon of central cooking and central linen distribution, and find it exceedingly satisfactory. However, instead of having service rooms on the ground floors, we have them on the top floor, which we have found to be a better arrangement, as there is practically no odor of food throughout the building, and there is less possibility of the help's carrying off food—no small item in the southern country. As in Bacon's plan, we have examining, operating and roentgen-ray rooms, the pathologic laboratory and the like on the top floor, which is conducive to efficient hospital service.

After our experience with private rooms, we would consider wards again only with reluctance, and would by far prefer to furnish the charity patients with one of our less expensive rooms rather than return to a ward plan, which is unsatisfactory both to the patient and to his attending physician.

GEORGE S. McREYNOLDS, M.D., Temple, Texas.

**NOTE ON RESPIRATORY SOUNDS
HEARD ON THE HEAD**

To the Editor:—These phenomena are recorded largely because I do not find any mention of them in the literature. At present I know of no clinical significance which they may have.

When the bell stethoscope is placed over certain points of the face and head, breathing sounds are distinctly heard. These places are, first, the antrums; second, the temporal portion of the scalp; third, the vertex along the median line; fourth, just medial to each mastoid and frequently over the mastoids themselves; fifth, at the junction of the occiput with the neck.

In many cases the breathing sounds may be heard all over the head, in other cases only in the places mentioned. There is a marked difference in the loudness of the sound heard, and, as might be expected, they are best heard on the heads of persons who have but little hair.

The quality of the sound is like that heard over the larynx, and probably represents a transmission along the

skull of the respiratory noises in nose, pharynx and larynx, that is, the upper air passages. I have stated that a bell stethoscope is best for hearing these sounds, but a Bowles may be used. The subject should be instructed to breathe deeply and regularly.

The phenomena are physiologic. That they may be of some significance in fracture of the skull and in diseases of the sinuses and the mastoid seems possible, *a priori*. I have not had the opportunity to study such cases, but take this opportunity of calling the attention of specialists in this field to these phenomena.

ABRAHAM MYERSON, M.D., Boston.

"THYROIDECTOMY IN PREGNANCY"

To the Editor:—In your editorial, January 13, page 329, occurs the question: "May premature delivery be associated with the milder grades of hyperthyroidism?" I believe that it is pretty generally conceded by students of the subject that hyperthyroidism produces premature delivery. I myself have observed a number of cases that seem to substantiate this opinion. The report of one of these cases I am quite sure was published, but I cannot just now cite the reference. It was a case of premature delivery from separation of the placenta, which separation, I concluded after careful survey of the case, was caused by a hyperactive thyroid. Crotti, in his book on "Thyroid and Thymus," page 368, speaking of exophthalmic goiter in pregnancy, says: "It predisposes the patient to uterine hemorrhages and may result in the death of the fetus."

MILES F. PORTER, M.D., Fort Wayne, Ind.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

SPIDER VENOM

To the Editor:—Will you let me know the name of the poison that causes the symptoms following the bite of a spider known as the "black widow," or, scientifically, *Latrodectus mactans*. I wish to know how and why this acts so violently on human beings. I have had three cases in the past few years. I have letters from Dr. Howard of the U. S. Department of Entomology, some from the Florida State Bureau, and one from Dr. Eugene Courson, Savannah, Ga., who wrote about the "widow" years ago. Dr. Courson has no extra copies of the paper. The two former told me about the distribution and gave me a list of references. None of them seemed to answer my question of what the poison is and how and why it acts as it does. Hence I am writing to you, as I was sure you would be able to help me out.

GEORGE D. KENNEDY, M.D., Mandarin, Fla.

ANSWER.—Little is positively known about the specific nature of the venom of spiders, although there has been much speculation. The venom is an oily, translucent, lemon-yellow liquid having an acid reaction and a hot, bitter taste. It gives the xanthoproteic reaction and is rendered harmless by heating to 90 C. In many ways the symptoms of spider bites resemble those produced by snake bites, so that it is probable that the spider venoms belong to that class of poisons. It is known that snake venoms are very complex mixtures and that they differ greatly in the different species of reptiles. Among the ingredients that have been found are fibrin ferment and antiferment, proteolytic enzymes, cytotoxins for red corpuscles, and neurotoxins, as well as leukocytes and endothelial cells. The marked effects on the nervous system produced by the bite of the black spiders, *Latrodectus mactans*, and other species of *Latrodectus* indicate that the venom of these animals resembles that of the cobra more nearly than the venoms of American snakes. Kobert believes that all parts of the spider contain a toxalbumin which in some species is mixed with the secretion of the poison gland. He considers that the secretion of the poison gland produces only local symptoms, while the general symptoms are due to the presence of this toxalbumin. It is because of the toxalbumin that the bite of *Latrodectus* is so

severe as occasionally to cause death in human beings. It contains a hemolysin called arachnolysin which acts on the red cells of man, rabbit, mouse and goose, but not on the horse, dog, sheep and guinea-pig. Some authors question whether the nervous symptoms following spider bites may not be due to changes in the blood rather than to a direct toxic effect on the nervous tissues.

HYPERHIDROSIS

To the Editor:—Some time ago you printed several prescriptions for the treatment of hyperhidrosis. Can you find these for me and tell me in what issue of *THE JOURNAL* they were published?

WILLIAM HILL BEAN, M.D., New Haven, Conn.

ANSWER.—The following prescriptions appeared in the Therapeutics Department of *THE JOURNAL*, Jan. 12, 1918:

	Gm. or Cc.
R Chromium trioxid	2 5
Water	50

Use as a paint once a week.

This treatment is said to be exceedingly active, and hence must be used with care, especially in the axillae. Less active but more pleasant than the foregoing is:

	Gm. or Cc.
R Tannic acid	5
Alcohol	100
Water	up to 200

Use as a wash twice a day.

The drying powders suggested were:

	Gm. or Cc.
R Boric acid	10
Purified talc	100

	Gm. or Cc.
R Salicylic acid	5
Bismuth subnitrate	40
Zinc stearate	20

	Gm. or Cc.
R Salicylic acid	2
Bismuth subnitrate	20
Starch	20

Other remedies suggested are: 25 per cent. solution of aluminum chlorid in distilled water; 2 per cent. solution of the official liquor formaldehydi in water (a 5 per cent. solution may be used for the feet); pure glycerin; potassium permanganate solutions of about 5 parts to 1,000. In very severe cases, the roentgen ray has been used with some good effect; however, the method is expensive and not entirely safe in unskilled hands.

DRY, WARM CLIMATE TO RETARD DEAFNESS

To the Editor:—I am unfortunate enough to suffer from partial deafness, due to catarrh of the nares, eustachian tube and middle ear. I realize that my hearing is becoming worse and that sooner or later I shall be incapacitated from doing medical work. I have treated with some of the best aurists in the East, have had my tonsils removed, septum straightened, tubes dilated and ears inflated, but without any permanent success. One or two aurists have replied, in answer to my query concerning the effect of climate, that my removal to some dry climate might aid my ears. I have endeavored to learn from the U. S. Public Health Service and the U. S. Weather Bureau of some of the localities in the United States where the climate may be suitable to my needs, but without success. It occurs to me that you may be able to give me the information I desire or may be able to refer me to some one who can. Or it might be that the publication of this letter will put me in touch with physicians who will give me the desired information. Whatever the course pursued to obtain the facts I want, I shall be glad to meet any expenses that may arise. I shall appreciate greatly any reply you may make or any thing you may do in this matter.

ROLLA CAMDEN, M.D., Parkersburg, W. Va.

ANSWER.—This communication is published for the purpose of bringing our correspondent's request to the attention of some reader who may be able to give him the information he seeks.

Massachusetts September Examination

Dr. Walter P. Bowers, secretary of the Massachusetts Board of Registration in Medicine, reports the oral, written and practical examination held at Boston, Sept. 9-11, 1919. The examination covered 13 subjects and included 70 questions. An average of 75 per cent. was required to pass. Of the 45 candidates examined, 35, including 4 osteopaths, passed, and 10, including 3 osteopaths, failed. One candidate, a graduate of Harvard University in 1915, passed a special examination held Sept. 24, 1919. The following colleges were represented:

Connecticut November Examination

Dr. Edwin C. M. Hall, secretary of the Connecticut Homeopathic Medical Examining Board, reports the written examination held at New Haven, Nov. 11, 1919. The examination covered 7 subjects and included 70 questions. An average of 75 per cent. was required to pass. One candidate was examined and passed. Two candidates were licensed by reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.

Social Medicine and Medical Economics

HOME AND PUBLIC HEALTH NURSES AND THEIR TRAINING

JOHN DILL ROBERTSON, M.D.

Commissioner of Health

CHICAGO

As this paper goes to press, we are in the midst of the 1920 outbreak of influenza.

Several days before the outbreak assumed epidemic proportions, the available supply of regular nurses was exhausted. For a period of days the calls for nurses poured in at the health department at the rate of fifty an hour.

At the offices of the School for Home and Public Health Nursing, two girls were kept busy at the telephone all the time taking calls for nurses trained in our eight-weeks course. Four hundred of our graduates took cases in private homes. Six hundred others, who were restrained by household duties from nursing full time, spent as many hours each day as they could spare in attending to the needs of the families in their neighborhood. All others, so far as I can ascertain, took care of their own ill, if they had any. Apparently there were no demands made on the regular nursing agencies by the families of any of our graduates.

THE DIFFICULTY OF SECURING NURSES

Every physician knows the difficulty of securing competent nursing care for the family in moderate or in submoderate circumstances. The difficulty has been steadily growing greater instead of less. There are various causes responsible for this condition. Foremost among them is the extension of the preliminary requirements for matriculation in a hospital for training. The nurse that is required to graduate from high school and spend three years in hospital training before she is eligible for registration feels that she cannot afford to work for less than \$35 a week. And she is quite right.

There is no question about the value of the registered nurse; her services are invaluable for those who can afford them. The trouble is that only those in very comfortable financial circumstances can afford them. When the family weekly income must cover fixed expenses such as rent, fuel, food, clothing, insurance, and so on, it is obvious that there is not sufficient left to cover \$35 a week and board for a nurse.

Physicians realize that disease is all too frequently the penalty of carelessness or of ignorance. Often it is the result of ignorance. There is no reason, however, why the victim should be too heavily penalized. His suffering is usually sufficient punishment for him. It is our duty to teach him as much as we can; but when a man is ill we should help first and teach afterward.

THE SCHOOL FOR HOME AND PUBLIC HEALTH NURSING

In August, 1919, we established in Chicago the School for Home and Public Health Nursing, both to teach and to help. The length of the course is two months. The pupils spend in class two hours a day for three days a week. We graduated 790 in the first class and 1,363 in the second class. Our third term opened, December 6, right in the midst of the fuel shortage incident to the coal strike. We found it necessary, therefore, to limit the size of the class to 1,000, and now have that number enrolled. We hope, however, to be able to make some arrangements that will enable us to admit a larger class in February.

At no time since the graduation of the first class have we been able to fill the calls for the services of these women,

in spite of the fact that we have not circularized the physicians of the city or in any way attempted to advertise their work. The calls for them have come in the main from the patients themselves, rather than from the attending physicians; but no dissatisfaction with their work has been expressed to me. Quite the reverse. As to the work they have been doing in their own homes I have, of course, no data.

In the beginning, our course aroused bitter opposition in some quarters. There is still some opposition; but this has never been sufficient to affect the work. Those who have spent three years in hospital training naturally feel that a nurse cannot be trained in two months—every one knows that a West Point graduate felt just the same way about a Plattsburg man. We do not, of course, pretend that the nurses we are training are the equal of registered nurses—that would be foolish, indeed. What we claim is that they can satisfactorily fill the need for nurses in the general run of cases in which all that is needed is some one to follow the physician's directions intelligently. In a critical surgical case, I should prefer a surgically trained nurse; surgical cases, however, make up a very small percentage of the cases that require nursing. For nursing tuberculosis, diabetes and cancer cases; nervous invalids, elderly persons, babies, children with measles, chickenpox, and, in fact, any children's diseases; for cases of tonsillitis, septic sore throat, colds, etc.—in short, for the great bulk of nursing, these women are quite as capable as the registered nurse. Often they are more desirable because they are willing to do housekeeping as well as nursing, and, in its final analysis, nursing is nothing more nor less than housekeeping for the sick.

THE CURRICULUM

Before we established the school, I called a meeting of the staff of the department of health. We discussed the curriculum of the standard nursing course with a view to determining what in the course was essential. As a result of this conference, we drew up a course of study for our school. Then we selected from our staff of physicians those who seemed best fitted to teach the subjects we had included in the course, and from our corps of city nurses we selected those who could best demonstrate the nursing technic we thought necessary.

The course included lectures on:

- The home nurse, her duties, qualifications and dress.
- The sick room.
- Daily routine care of the patient.
- Giving medicine and home medicine equipment.
- Temperature, pulse and respiration.
- Uses of water as a therapeutic agent.
- Symptoms of sickness.
- First aid to the sick.
- First aid to the injured.
- Poisons and their antidotes.
- The human body.
- Food.
- Food for the sick.
- Sanitation of the home.
- Plumbing and the housewife.
- Contagious diseases.
- Causes, symptoms and prevention of contagious diseases.
- Principles of contagious disease nursing.
- Nursing care of influenza.
- Nursing care of patients suffering from tuberculosis.
- Obstetric nursing.
- Care of the baby.
- Care of the older child.

Our demonstrations included bed making, bathing, sponging, taking temperature, pulse and respiration, bandaging, first aid, etc.

We placed most emphasis on the taking of temperature, pulse and respiration. We held temperature, pulse and respiration clinics. Every pupil was required to provide herself with a clinical thermometer. We taught them to take temperature by mouth, by rectum and by axilla; and we didn't let one go until she could take temperature and read her ther-

nometer correctly. Many of them learned in a short time, others were slower. The hardest two weeks of the course, so far as the instructors were concerned, were the two weeks when we were drilling on this subject.

The lectures on contagious disease nursing were given by the nurse in charge of the work at our contagious disease hospital. The lectures on obstetric nursing were given by a woman who had spent twenty years in that sort of nursing. The lectures on the nursing of the tuberculous were given by experts in this line from the Municipal Tuberculosis Sanitarium, and augmented by lectures by the medical director of that institution. And so on with the other lectures—each was given by the best talent that we could command. No one who lectured did so from theoretical knowledge alone.

Throughout the course we hammered on two main propositions—absolute adherence to the physician's orders, and cleanliness. In order to show them what a physician means by cleanliness, I arranged that every woman who attended the lectures should be given a chance to see at least one surgical operation from a hospital amphitheater. They were visibly impressed by the precautions taken by the surgeon and his assistants to secure absolutely aseptic conditions. Clean hands

TABLE 1.—DATA CONCERNING THE FIRST TWO CLASSES

Ages:	No.
Under 20	81

no longer mean to those women what clean hands meant to them before they saw the surgeon and his assistants scrub up.

It is no part of the duty of a nurse either to diagnose or to prescribe. In our lecture on the "Symptoms of Disease" we endeavored to teach them what symptoms indicated the presence of a condition that should be brought to a physician's attention; we made no attempt to teach them to read the meaning of the symptoms. We taught them that when they found a high temperature associated with an abnormal pulse they were to summon a physician at once. We taught them that any abnormal condition of the excretions of a person, whether a patient or one apparently in good health, should be brought to the attention of a physician. We tried to make clear to them that it was wise to have a physician overhaul the physical mechanism as soon as there was even an apparently trifling indication of trouble rather than to wait to see whether something worse would develop. Our idea in this was to have these women become the guardians of the health of their families first and to act as their nurses secondly.

In our lecture on "Giving Medicine," we emphasized the importance of absolute adherence to the physician's orders. We made not the least attempt to teach the women to prescribe; on the contrary, we tried to make clear to them the danger of attempting to prescribe even castor oil of their own accord. There is no other place in the universe where a

little knowledge is so truly a dangerous thing as in medicine. These women know that they know nothing about materia medica—at least we told them so often enough.

Our aim throughout has been to train them enough to enable them to follow the physician's orders explicitly; but not enough to make them think they can assume any part of the duties of the physician.

In order that there might be no mistake as to what they had been taught, we collected the lectures from those who gave them and incorporated them in an official note book. We gave a copy of this note book to each nurse we graduated.

TABLE 2.—SALARIES DESIRED BY EIGHT HUNDRED AND SEVENTY-TWO GRADUATES WHO ARE WILLING TO WORK OUTSIDE THE FAMILY

	No.
Willing to work for from \$10 to \$15	7
Willing to work for from \$15 to \$18	82
Willing to work for from \$18 to \$20	163
Willing to work for from \$20 to \$25	618

USE MADE OF THE TRAINING

Many of the women we have trained have no intention of doing any nursing outside of their own families. The figures given in Table 2 will be of interest. Whether they nurse their own families or their neighbor's families, however, makes little difference in the final result. If Mrs. Brown can nurse her own sick, the nurse who would otherwise be on duty in her home is released for work elsewhere. The homes in which there are neither babies, children nor elderly persons are few and far between. Where there are none of these to tax the family income, the family can probably afford to pay for the services of a registered nurse in case of illness in the household. Where there are babies, children or elderly persons, the nurse is always likely to have enough to do to keep her busy at home.

We started the school when we did in order to be prepared for a possible recurrence of the influenza epidemic that swept our country during the winter of 1918-1919. A great many of the women that we have trained can be depended on to come to our aid in time of need, such as a recurrence of the epidemic would cause. When I say that they are unwilling to do nursing outside of their own homes I mean ordinarily, not during an epidemic.

Many of our graduates want more knowledge, as witness the data given in Table 3.

TABLE 3.—GRADUATES WHO DESIRE FURTHER INSTRUCTION

	No.
Registered for extension courses	1,222
Willing to enter hospital:	
For three months	225
For one year	50
For two years	8
For three years	35

CONCLUSION

The prophet's job is a thankless one, consequently I shall not attempt to prophesy the final outcome of the movement that we have undertaken. I shall, however, state that I expect to have trained 10,000 women in our school by the end of the first year of its existence. Ten thousand nurses sounds like a drop in the bucket in a city of two and a half million; but 10,000 such nurses would have saved many lives if we had had them during our epidemic in 1918. Moreover, it is a start, and every one knows that a task well started is half finished. Eventually, I should like to have every housewife in Chicago in our class room, not so much to train her to

nurse the sick as to train her to keep her family well. In my mind there is no doubt that preventive medicine will supplant our present system of remedial medicine in the near future. When every man pays his physician to keep him well instead of to get him well, there will be little need of health commissioners. I am trying to do my part toward bringing about such a state of things.

Let me repeat, it is no part of our plan to run in opposition to the registered nurse. There will always be a field for her. It is our plan to train a body of housekeepers for the sick, practical nurses, attendants—whatever you want to call them—who will competently carry out the physician's directions in that great bulk of cases in which it is out of the question to pay for the services of a registered nurse. We are training soldiers to serve under the leadership of the physician in the fight against disease; we are not training subofficers.

I should like to see a similar movement undertaken by every health department in our land, and can promise the help of my department to the extent of our resources to any one who desires it.

Book Notices

VENEREAL DISEASES: A PRACTICAL HANDBOOK FOR STUDENTS. By C. H. Browning, M.D., D.P.H., Director of Bland-Sutton Institute of Pathology of Middlesex Hospital, and David Watson, M.B., C.M., Lecturer on Venereal Diseases, Glasgow University, with an Introduction by Sir John Bland-Sutton, F.R.C.S. Cloth. Price, \$6.50. Pp. 336, with 76 illustrations. New York: Oxford University Press, 1919.

This manual gives an outline of our knowledge of syphilis in 140 pages, and then of gonorrhea, in almost the same amount of space. The presentation is up to date, scientific, well written, and orthodox. As one of the authors is a laboratory man who has done considerable work on syphilis, the book goes with more than ordinary detail into the laboratory side of these diseases. This is altogether to be desired. The consideration of the diseases, furthermore, is not confined to either genital or skin manifestations: the systemic manifestations of both syphilis and gonorrhea are given due consideration. Although the book is called a handbook of venereal diseases, chancroid, curiously enough, is given no formal consideration, being taken up incidentally in connection with the diagnosis of syphilis. It is entitled to more consideration in a book on venereal diseases. The make-up of the book is good. Some criticism is to be made of the illustrations. The clinical illustrations in black and white are not as good as we are used to, and many of the colored clinical illustrations, which are made from color photographs, are poor. A few are quite lifelike. The book has the great merit of being concise and not burdened with unnecessary details. It can be highly recommended as a guide to a practical knowledge of syphilis and gonorrhea.

PLASTIC SURGERY: ITS PRINCIPLES AND PRACTICE. By John Staige Davis, Ph.B., M.D., F.A.C.S., Instructor in Clinical Surgery, Johns Hopkins University. Cloth. Price, \$10 net. Pp. 770, with 864 illustrations. Philadelphia: P. Blakiston's Son & Co., 1919.

It is the author's opinion that "the field of plastic surgery extends from the top of the head to the sole of the foot, and no properly trained plastic surgeon would be willing to limit his work to the face alone"; as a result, he has assembled between the covers of one book a summary of restorative and reconstructive surgery dealing primarily with defects of the surfaces of the body, including harelip and cleft palate, hypospadias, and exstrophy of the bladder. Wound infection, burns, deforming cicatrices, chronic ulcers and the general principles of tissue transplantation, with especial reference to the transplantation of skin, are among the subjects receiving thorough consideration. There is little to criticize unfavorably, and much to commend. The style is clear and convincing; there is no verbosity, and yet when the author has discussed a subject there are few places where the admirable brevity of the text permits of ambiguity

or misinterpretation. The illustrations are numerous, well executed and labeled with a thoroughness rarely seen in textbooks, but which should be much appreciated by those who may wish to use this book as a guide. An abundant and possibly top-heavy bibliography appears at the end of each chapter. The author has what might be called the definitive adjective habit. Like many other medical writers, he speaks of an appendicitis, a pneumonia, a necrosis, apparently being unable to overcome the habit of interjecting the unnecessary word. From a scientific standpoint the book is excellent, and should find a place in every medical library.

MEDICAL SCIENCE: ABSTRACTS AND REVIEWS. Monthly. Published for the Medical Research Committee by the Oxford University Press. Price, \$8.50 per annum.

This publication is an outgrowth of one published during the war under the auspices of the Medical Research Committee to keep British military physicians informed concerning advances in medical science as revealed in periodical literature. The publication includes collective abstracts on various subjects as well as abstracts of single articles which have seemed to the editors to be of special importance. The editors are: medicine, J. D. Rolleston, M.D.; surgery, W. G. Spencer, M.S., F.R.C.S.; pathology and bacteriology, W. Bulloch, M.D., F.R.S.; neurology, F. M. R. Walshe, M.D., and radiology, W. S. Lazarus-Barlow, M.D., F.R.C.P., and Sidney Russ, D.Sc. In addition to covering the field as did the German "Centralblatts," the editors of the various departments do not seem to be bound to local or national schools of medicine, but have consulted freely the periodical literature of all nations.

PHYSICAL DIAGNOSIS. By Richard C. Cabot, M.D., Professor of Medicine in Harvard University. Seventh edition. Cloth. Price \$4. Pp. 527 with 269 illustrations. New York: William Wood & Co., 1919.

In his preface, Dr. Cabot states that new experiences gained during the war have modified his ideas on the cardiac signs of nervousness, on hilum tuberculosis, on goiter heart and on empyema. New matter has been supplied on these subjects. He also states that he has developed great skepticism "as to the existence of rheumatic mitral regurgitation (without stenosis), as to the diagnosis of chronic appendicitis and of tricuspid stenosis." He has also presented some new views on the subject of arterial sclerosis and blood pressure. Beyond these points, the book appears much as usual. It is well printed, with numerous illustrations, and is a reliable textbook.

Medicolegal

Liability for Negligent Advice to Parents of Scarlet Fever Patient

(*Skilling v. Allen* (Minn.), 173 N. W. R. 663)

The Supreme Court of Minnesota, in affirming an order overruling a demurrer to the complaint in this case, holds that a physician may be liable to a parent of a patient for damages sustained by such parent from negligent advice given by the physician, as when the patient had scarlet fever. In other words, the court holds that a complaint states a cause of action when it is alleged therein that the defendant, a physician, was employed by the plaintiff to attend his minor daughter professionally while she was sick; that, knowing that the child's disease was scarlet fever, he negligently advised the plaintiff's wife, who inquired in his behalf as well as in her own, that it was safe to visit the child, then in a hospital and under the defendant's care; that he also advised her that it was safe to remove the child from the hospital to the plaintiff's home, and that there was no danger that the disease would be communicated, although it was then at a stage when great danger of infection existed; that the plaintiff and his wife did not know of the infectious nature of the disease and relied on the defendant's advice, and accordingly visited their child at the hospital

and removed her to their home, and the plaintiff thereby contracted scarlet fever, to his damage.

The court says that the case was a novel one, wherein it had been certified that the question raised was important and doubtful, and counsel for the defendant asserted that no case like it had before been presented to any court, so far as they had been able to ascertain. Counsel contended that a cause of action was not stated because there were no contractual relations between the plaintiff and the defendant. But the statement in the complaint, that the child was under the defendant's care "pursuant to solicitation and employment by the plaintiff and his wife," amounted, the court thinks, to an allegation that there were such relations. True, the child was the defendant's patient; but can it be said that therefore he owed no contractual duty to her parents by whom he was employed? The child would have a cause of action against the defendant for the consequences of any failure on his part to treat her with ordinary professional skill and care, though she did not employ him. The plaintiff might also have a cause of action entirely separate and apart from that of his child for the loss of her services, due to the same failure to exercise ordinary professional care which gave rise to the child's cause of action. Generally speaking, one is responsible for the direct consequences of his negligent acts whenever he is placed in such a position with regard to another that it is obvious that if he does not use due care in his own conduct he will cause injury to that person. This principle was applicable to the fact stated, and the demurrer to the complaint was properly overruled.

Assuredly this was a case in which there was every reason to hold that the defendant was under a legal duty to the plaintiff, and it was of little practical consequence whether the duty was called contractual or noncontractual. The health of the people is an economic asset. The law recognizes its preservation as a matter of importance to the state. To the individual nothing is more valuable than health. The laws of Minnesota have been framed to protect the people, collectively and individually, from the spread of communicable diseases. Scarlet fever is classed as such a disease. When the defendant discovered that the plaintiff's child was suffering from an infectious disease, it became his duty to comply with the laws of the state in order that the public health might be protected. His duty did not stop there. The child's parents were naturally exposed to infection to a greater degree than any one else. To advise them that they ran no risk in visiting her at the hospital or in taking her into their home necessarily exposed them to danger if they acted on the advice, and the defendant was bound to know that they would be likely to follow his advice. It was allowed that the advice was given negligently, and all the necessary elements of a cause of action based on negligence were present.

The court concludes that the complaint was not demurrable, although it might be true, as suggested, that it is a matter of common knowledge that scarlet fever is an infectious disease and that the plaintiff might not have been greatly influenced by the defendant's alleged assurance that he might visit his child or take her to his home without running any risk of infection.

Osteopathy and the Practice of Medicine

(*In re Opinion of the Justices (R. I.)*, 107 Atl. R. 102)

The Supreme Court of Rhode Island, in giving the opinion, in answer to a question in regard thereto submitted by the governor, that persons who have received certificates to practice osteopathy from the state board of health, and who have registered in the town clerk's office of the city or town in which they reside their authority for so practicing, are legally entitled to sign death certificates in those cases in which they were last in attendance professionally on the deceased, says that it thinks the conclusion reached is strengthened by a consideration of the result if the other construction were adopted. In that case we should have this situation: The state by its examination and certificate has certified to the ability of the osteopath to discover the cause

of the disease while the patient is alive; but, on the death of the patient, the osteopath then is to be held to be incompetent and unauthorized to state the cause of death. Such a construction is illogical, and its effect would be to impose in many instances unnecessary hardship and pain on the relatives of the deceased. It cannot be doubted that the practice of osteopathy as authorized by Chapter 1058 of the Public Laws of 1914 is the practice of medicine within the meaning of those words as used by Section 8 of Chapter 193, by which penalties are provided for the unlawful practice or attempt to practice medicine or surgery or any of the branches of medicine or surgery. The statute authorizes the licensed practitioner of osteopathy to make a diagnosis of diseased or abnormal conditions of the human body and to apply a remedy therefor. This power of diagnosis is not restricted. Having determined, however, the nature and the cause of the sickness, the practitioner is then restricted to the remedy for the ailment which must be confined to manipulation of the body; the method and the extent of the manipulation is left to the judgment of the practitioner. But in some parts of the statutes the word "physician" undoubtedly does have the limited meaning of doctor of medicine, and not the broader meaning; as in Chapter 123, Section 54, by which it is provided that liquors are not to be sold, etc., except on a physician's prescription; and in Section 17 of Chapter 178, "Of Medicines and Poisons," where it is provided that any physician who shall prescribe certain drugs, etc. As osteopaths have no authority to give prescriptions or to prescribe drugs, it is manifest that the word "physician" in these clauses does not include a practitioner of osteopathy.

Demand for Injection of Collargol Not Reasonable

(*United States Fidelity & Guaranty Co. et al. v. Wickline (Neb.)*, 173 N. W. R. 689)

The Supreme Court of Nebraska holds that, when a woman employee who has suffered an injury to one of her kidneys offers to permit a roentgenogram of the kidney to be made, but refuses to permit the injection of collargol into the kidney for the purpose of rendering it opaque, she does not necessarily, by such refusal, forfeit her right to compensation under the employers' liability act. The court says that in a former opinion it stated that, in the present advanced state of the science of roentgen-ray examinations and photographs of the person, there appears to be no reason why such examination or photograph should not be permitted by a claimant for compensation under the employers' liability act, on request by the employer or insurer, unless the request is shown to be unreasonable. The district court was therefore required to determine whether under the circumstances the request in this case was reasonable. A physician skilled in the art of making and reading roentgenograms testified that in order properly to determine the extent and character of the defendant's injury a roentgenogram of the kidney ought to be made, and that in order to make a proper roentgenogram it might be necessary to inject collargol into the kidney. In the hands of an expert, he said, there is no danger whatever; but that procedure is not used as extensively as formerly, because of ability now to roentgenograph the kidney without it, though he found it necessary to use the solution in a few cases. The defendant testified that if the court called on her to have a roentgenogram taken, she would permit that to be done; but she would refuse to have collargol injected into her kidney. The district court found that the demand on her was not reasonable, and that her refusal ought not to bar her from a recovery of compensation under the employers' liability act; and the supreme court is constrained to hold, with the trial court, that the demand on Mrs. Wickline was not reasonable. It will be seen from the testimony produced by the plaintiff, the supreme court says, that it is only in rare instances that it is necessary to inject this substance into the kidney, and it would seem that the plaintiff ought to have availed itself of the defendant's offer to submit to a roentgenoscopy without this injection. It might be that an injection was not necessary.

Society Proceedings

PHILADELPHIA COUNTY MEDICAL SOCIETY

Meeting held Jan. 14, 1920

The President, DR. J. FRANKLIN STAHL, in the Chair

The Question of Dental Infection in the Production of Nervous and Mental Diseases

DR. CHARLES K. MILLS: Fortunately, the mind of the profession seems to be tending toward a very healthy discussion of the probable fallacies of dental infection in its relation to various important diseases, and of many other correlated and zealously exploited views. Shortly after the death of Colonel Roosevelt, a newspaper article appeared which illustrated one of the most dangerous forms of medical propaganda. It was stated that one of Colonel Roosevelt's teeth was the indirect cause of his death, and that thousands of persons die or are incapacitated yearly from maladies arising from infected teeth. The cases of a rescued backward boy whose brain was clouded to the point at which he could not master the rudiments of knowledge, and a youth assailed with a lethargy at the age of 15, who afterward became one of the most brilliant lawyers of the Middle West, were included in a series of cases supposedly illustrative of the marvelous results of the removal of infected teeth. I have but little doubt that literally bushels of teeth of excellent quality have been sacrificed as the result of this atrocious article about Colonel Roosevelt. Viewing roentgenograms, I have been skeptical as to what are designated as abscesses at the roots of teeth. It has always seemed to me that these pictures represented absorptive lacunae or artefacts of some other description, rather than true abscesses. The roentgen ray enables us to discriminate between areas of differing density. In a strict sense an abscess cannot be demonstrated by a roentgenologic investigation. A score or more of cases have come to my knowledge in which important mental and nervous diseases have been attributed to dental infection, and in which the teeth had been removed with results in some instances so harmful as to make me feel that the procedure was almost a criminal one. Dr. Cotton, one of the leading psychiatrists of the country, attributes many and diverse forms of insanity to dental infection. The late Dr. August Hoch, in a critical review of one of Dr. Cotton's articles, clearly points out the logical defects in the presentation. Under the influence of the propaganda of focal infection, to use the expression of Dr. Peterson, the colons of epileptics bid fair to be reduced to semicolons by operation. The appendix will soon no longer be a vestigial illustration, and the tonsil, protrusive and submerged, is sharing the fate of the ovary in our early experience. A nose and throat specialist not long ago gravely informed me that he thought of preparing a statute to be presented to the state legislature making compulsory the extirpation of the tonsils of children after reaching a certain age on the theory that prevention is better than cure. On the same principle may not our exodontist friends be called in for their exterminating activities, and thus free the rising generation of teeth which in the course of time may have their roots infected and abscessed? I protest against the too free use of the therapeutics of organic mutilation. If the craze for violent removal goes on, it will come to pass that we shall have a gutless, glandless, toothless and perhaps, thanks to psychology and surgery, a witless race.

Dental Therapeutics Based on Clinical and Roentgen-Ray Investigations

DR. WILLIAM MIDDLETON FINE: As a dentist I am forced to believe that too many teeth are extracted in the expectation that their removal will cure systemic disturbances. Because it is possible to demonstrate the same micro-organisms in pulpless teeth and in arthritic joints, it should not be stated that the teeth are invariably the primary cause of the infection. The extraction of badly decayed teeth with root abscesses, or their restoration to health and usefulness,

removes one of the contributing factors in the cause and development of many diseases. I do not share the belief that all nonvital teeth should be removed. Our bodily protective processes prevent well treated teeth, without living pulps, being the direct cause of disease. Talbot would lead us to believe that all the shadows in roentgenograms of dead teeth are not abscesses, and that these teeth should not be extracted ruthlessly. I agree with those who advise the extraction of dead and diseased teeth after a thorough attempt to effect a cure has failed or is doubtful. It is more than likely that 75 per cent. of the shadows in the roentgenograms at the apical ends of teeth have been caused by irritation from mechanical treatment and the use of drugs in dental operations, and hence these teeth are removed unjustifiably. I have seen teeth that roentgen-ray examination indicated were abscessed—as some men would say—remain fifteen years or longer without any symptom of disease, local or general. I received recently three cards from men announcing that they were giving up general practice to specialize in extraction of teeth. We do not need three new extractors every week.

Present Status of Oral Sepsis in Relation to Systemic Disease

DR. JAMES M. ANDERS: The importance of the relation of tooth root infection to systemic diseases cannot be overemphasized from the point of view of study and investigation. Our knowledge of the flora of the mouth, as related to special affections, is still imperfect. A closer cooperation between dentist and physician, along bacteriologic lines, is urgently needed to deal intelligently with affections of the teeth and alveolar processes, and to correct the haphazard sacrifice of the masticating apparatus. I recall a case, one of epilepsy, in a young woman, aged 19, in which, on the advice of a physician, all the teeth, although in good condition, were extracted, without, of course, any effect on the epilepsy. It behooves physicians and dentists to oppose the appalling present rate of removal of teeth. It has been shown that after the fortieth year of life, disseminated infections leading to constitutional disturbances are more frequent and of more serious character than in younger subjects. That many morbid medical conditions may be of oral origin is shown in their cure following the removal of the foci of oral infection. Among many such medical conditions are arthritis, endocarditis, pericarditis, myocarditis, gastritis, myocardial degeneration, chronic nephritis and exophthalmic goiter. Gingival and dental diseases, however, are rarely the sole cause of the morbid states for which gums and teeth may be held responsible. Before teeth are condemned, it is a matter of vital importance to determine that other than oral infectious foci are not present. Treatment based on roentgen-ray studies alone is unwise, since the deeper dental lesions may be simulated by other local conditions, and an abscess which actually exists may not be shown. The local and clinical features are to be noted carefully, and extreme caution should be observed in ascribing a systemic infection to the mouth condition. Bacteriologic study is essential in oral infections. Sanitary oral cavities are potent factors in limiting the incidence and spread of communicable diseases.

Roentgen-Ray Studies of Dental Defects

DR. HENRY K. PANCOAST: The roentgenologist is not able to judge of the direct connection between dental conditions and their supposedly resultant systemic conditions. This is the work of the internist. Not all "clear areas" are due to abscesses at the roots of teeth. Some may be due to old infections, others to chemical irritants. If read properly, however, most of these "clear areas" represent active abscesses. I am opposed to the wholesale extraction of teeth. In many instances it is possible to treat abscessed teeth successfully and have good service from these teeth afterward. An abscess may be present at the root of a tooth and not show in the roentgenogram, but that is a rare occurrence. Experience in the interpretation of the roentgenograms is more important than the technic, and such interpretation is best carried out by the dentist and the roentgenologist in collaboration.

Surgical Renal Tuberculosis.—Coincident active pulmonary tuberculosis was found by Braasch in approximately 5 per cent. of his patients, of whom more than 60 per cent. recovered following nephrectomy. Involvement of genitalia was present in at least 73 per cent. of male patients but did not seem to affect the ultimate recovery. Frequency of spontaneous healing of lesions in the prostate and seminal vesicles contraindicates their removal by subsequent operation. Evidence of tuberculosis involving the bones and joints was noted in 6 per cent. of the cases; one half of the lesions were active. The late mortality was 5 per cent. from which it may be inferred that the presence of such complications may be an index of increased resistance. Spondylitis, usually healed, was present in 5.7 per cent., with a mortality of 12 per cent. Tuberculous adenitis was present in nineteen patients (6.4 per cent.) and the low mortality (10 per cent.) is suggestive of a heightened resistance. The operative mortality is a negligible factor; the late mortality (five years or less after operation) is approximately 20 per cent.; failure to effect complete cure is approximately 20 per cent.; this leaves a prognosis of recovery in 80 per cent. and of a complete cure to be expected in fully 60 per cent. of patients.

Pharmacology of Certain Drugs.—A number of drugs were studied by Bastedo and some of his findings in the use of the more important ones were as follows: In the ordinary hyperacidity case, with cessation of secretion at the usual time, atropin or belladonna, in maximum doses, either by mouth or hypodermic, had no useful effect on acidity or secretion. In hyperacidity cases atropin had no useful effects in any dosage. In continuous hypersecretion cases it may check the secretion after the digestive period, but it does this in maximum doses only. In pylorospasm it may be useful, but in maximum doses only. In the doses usually employed, it is wholly without effect on the secretory or the motor function of the stomach. In cases of achylia gastrica, whether or not accompanying pernicious anemia, a deficiency of acid may be partially overcome by hydrochloric acid medication. For digestive purposes, hydrochloric acid should always be accompanied by pepsin. In the achylia with diarrhea, acid promises a more noticeable result than in the achylia without diarrhea. When acid produces sourness and stomach irritation, its use should not be continued. To avoid acidosis alkalis should be given during the same period, though not at the same time as the acid, the amount required being judged by the effect on the urine reaction. A bitter is useful as an appetizer for those with subnormal nutrition, as in convalescence from acute illness, provided, that it is taken not more than five or ten minutes before the time for eating. It acts in achylia gastrica as well as in cases with gastric secretion. In subacidity it promotes the secretion of gastric juice. It should be administered in just

sufficient dose to give a strong bitter taste, and not in amounts large enough to have a depressant action in the stomach. If the patient is in a state of normal nutrition, but psychically disturbed about eating, it will be useless. If the appetite is already normal the bitter may not only fail to increase appetite but may even lessen it. If the stomach and bowels are deranged, bitters may nauseate. The effect on appetite is solely the local one on the taste buds, therefore, it cannot be obtained if the bitters are hidden in capsules or coated pills.

Roentgen-Ray Diagnosis of Perinephritic Abscess.—Cases are cited by Fussell and Pancoast to show that the roentgen ray will aid in the diagnosis of perinephritic abscess. In the first case cited, this fluid was demonstrated while the patient was standing in the fluoroscope. The shoulders of the patient were grasped and the patient's body moved quickly two or three times from side to side. Watching the fluoroscopic picture showed a distinct wave in the supposed fluid. The renal region was opened and a huge sac of pus was demonstrated within the capsule of the kidney.

Effects of Diets on Gastric Secretion.—The study made by Crohn and Reiss shows that medical treatment, consisting of restricted diet and rest in bed, causes the cessation of hypersecretion in 45 per cent. of cases, a fair proportion; clinical improvement takes place as often in cases with persistent hypersecretion as in those relieved of their excessive flow of gastric juice, and is apparently not dependent on it. Cases that fail to show clinical and chemical improvement are of two kinds, patients with advanced indurated ulcers which are resistant to treatment and those with a marked neurosis. The first class can be reduced in number by more persistent and more protracted treatment. The second group requires the expert care of a neurologist, often of a psychoanalyst. Mistakes in diagnosis undoubtedly form a third group of not inconsiderable proportion. The beneficial effects of medical treatment are seen in those cases of hyperacidity, hypersecretion and pylorospasm accompanying latent cholelithiasis or chronic appendicitis, as well as in ulcer cases or functional secretory disturbances.

Action of Digitalis on the Heart.—This paper was abstracted in THE JOURNAL, Aug. 30, 1919, p. 715.

- Protein and Lipin Contents of Blood Serum in Nephritides. M. Kahn, New York.—p. 112.

Shallow Breathing and Pneumonia.—A number of cases of pneumonia were investigated by Meakins in order to determine the quantity and quality of the expired air. It was found that as the respiratory rate increased there was a gradual decrease in the volume per respiration, but the total ventilation per minute showed a conspicuous increase. Meakins believes that the conclusion is justified that the anoxemia occurring in acute lobar pneumonia is the result of the rapid and shallow breathing typical of this condition.

Physiology of Stomach.—Ivy reports the results of his studies on gastric ulcer, including studies on the pathologic physiology of the stomach and duodenum in the condition of ulcer of these parts of the gastro-intestinal tract.

Roentgen Rays and Cancer.—Of forty-one cases studied by DeNiord and his associates, thirty-four, or 83 per cent., showed a varying excess of total fat in the blood before exposure to the roentgen rays. One-half hour after exposure to the roentgen rays, the first findings were increased in thirteen cases, and decreased in twenty-eight cases. Twenty-four hours after treatment with the roentgen ray, the first findings were increased in six cases and decreased

in thirty cases. Thus, the total fat content was diminished in 83 per cent. of his series of cases after exposure to the roentgen ray, and in some cases the decrease was preceded by a slight rise of the total fat quantity. Urea, urea nitrogen and creatinin showed nothing characteristic of the cancer patient. The moderate uric acidemia which exists for a short period of time after exposure to roentgen rays the others claim is the result of nuclear degeneration, but is not especially characteristic of malignancy. The sodium chlorid content of cancer patients is altered neither by the presence of the tumor nor the exposure to roentgen rays. The cholesterol, fatty acids and total fats are generally increased in cases of malignancy. Cholesterol is increased in the blood, but this is not in proportion to the duration of exposure to the roentgen ray or varied as to the type of tumor. The increase of cholesterol in the blood is probably due to cellular autolysis with liberation of cholesterol, induced by the action of the roentgen rays. Fatty acids and total fats are consistently high in the blood of cancer patients and this increase is reduced by the roentgen rays. The authors do not give any reason or hypothesis for the reduction, as they are at present carrying on further studies along this line. The final conclusion arrived at is that there is nothing in the behavior of the blood sugar or diastatic activity that is diagnostic of cancer. However, the roentgen rays activate the diastase for a short period of time to a greater than normal activity. The plasma and corpuscle percentages were unaltered by the effect of the rays, hence are of no diagnostic value in cancer.

Cerebrospinal Fluid in Multiple Sclerosis.—The cerebrospinal fluid findings in twenty-eight cases of multiple sclerosis are reported by Moore. In twenty cases the diagnosis is clinically certain; in the other eight cases it is clinically doubtful. In the first group, the findings are (a) negative blood and spinal fluid Wassermann (all cases); (b) pleocytosis (eight cases); (c) positive globulin (eighteen cases); (d) paretic gold curve (eighteen cases). In the second group the findings are the same, except for the gold curve, which was syphilitic in three cases and negative in five cases. Together with the clinical evidence, it is believed that the spinal fluid picture is fairly constant, and that, other things being equal, such a picture is a strong argument in favor of a diagnosis of multiple sclerosis. In its absence the diagnosis becomes at least doubtful.

Pulmonary Tuberculosis.—There are three conditions, Honeij says which at times may be confused and which make a differential diagnosis difficult or often impossible. These include (a) true cavitation in pulmonary tuberculosis, with and without fibrous walls; (b) true pleural annular shadows, with and without pulmonary disease; (c) false annular shadows of intrapulmonary bronchial origin, occurring in early pulmonary tuberculosis and other chest conditions. These three conditions are illustrated. A clear understanding of the pathologic processes involved, thorough appreciation of the different clinical signs is needed, and since, in a broad sense, physicians are less interested in the presence or absence of cavitation than in its effect on diagnosis, treatment and prognosis, it is essential carefully to consider other acute or chronic lung lesions in conjunction with the direct evidence of cavitation.

*Tissue Injury an Important Factor in Development of Tuberculosis. H. F. Gammons, Dallas, Tex.—p. 119.

Injury of Tissues and Tuberculosis.—Gammons reports four cases in which he believes that injury was an important factor in determining the localization of the tubercle bacilli. Two of the patients fell and injured the knee. Several years later tuberculosis of the knee was diagnosed. In the third case, the patient was kicked by a horse in the vicinity of the right ilium. An abscess formed later and the pus was positive for tubercle bacillus. Tuberculosis of the ilium was found. The same patient injured the right ankle. It, too, became tuberculous. The fourth patient sustained a contusion of the right hand. Tuberculosis of the small bones developed. All of these patients also had a pulmonary tuberculosis.

Conservative Surgery. O. O. Melton, Hammond.—p. 14.

Value of Roentgen Ray in Diagnostic Work.—While McCaskey appreciates the value of roentgen-ray examinations and other aids to diagnosis, he emphasizes the fact that these methods never make a complete or rational diagnosis but are simply factors, albeit sometimes indispensable factors, in the general diagnostic judgment. He fears that roentgenologists are often pressingly solicited by physicians for specific diagnostic judgments, and that they too often yield to the importunity when they should make it plain that their duty is done when they give an objective description of their findings. So common has it become for roentgenologists to attempt to arrive at diagnostic conclusions from their studies alone, that it is sometimes difficult to get from them the objective description that one desires, either alone or accompanied by a diagnostic impression. Instead, the reports of "chronic infectious arthritis," "pulmonary tuberculosis," or some other diagnosis come in. McCaskey believes that this unsatisfactory state of affairs will soon be remedied so that roentgenology and internal medicine will reciprocally benefit one another to the utmost.

Determination of Saccharin in Urine.—The method described by Jamieson is based on the quantitative extraction of the saccharin with ether from the acidified urine which had been previously treated with normal lead acetate and filtered. After acidifying with hydrochloric acid, the saccharin is extracted by ether, the ether removed by evapora-

tion, and the saccharin extracted from the residue with ether. The ether is removed and the resulting residue is fused with sodium carbonate and the sulphur determined as barium sulphate. The amount of saccharin is calculated from the sulphur found after making a correction for the blank. The experimental results obtained by the analysis of urines, to which known amounts of saccharin had been added, show that the method is capable of giving satisfactory results, providing that the directions are followed exactly as described in every detail.

Citric Acid in Tomato.—The presence of citric acid in tomato juice was shown by Kremers and Hall by means of its triphenacyl ester.

Carbohydrate in Certain Vegetables.—Vegetables usually used in low carbohydrate diets for diabetic patients were analyzed by Olmsted by the use of diastase and copper reduction, and by feeding to phlorizinized dogs. The results are given in detail.

Effect of Hemorrhage on Alkaline Reserve and Blood Sugar.—The results of the experiments described by Tatum appear to indicate that hemorrhage produces a rise in blood sugar by changes in the state of acid-base balance in body cells, which state is fairly well reflected in corresponding changes in the general circulation. The chief seat of action is probably the liver, for this is the location of glycogen storage most readily affected.

Hemoglobin as Means of Identifying Species.—From the results obtained by Welker and Williamson, it would appear that there is not sufficient difference in the absorption coefficients of the hemoglobin of various species to serve as a means of identification of the species. This finding confirms the conclusions of most previous investigators.

Protein Requirement of Maintenance.—Sherman states that even when the protein of the food is almost entirely derived from bread or other grain products, with a diet adequate in energy value, a daily intake of about 0.5 gm. of protein per kilogram of body weight is sufficient to meet the actual requirements of maintenance in healthy men and women. While, if numerous older experiments, having a tendency to high results, are included, the average is somewhat less than 0.66 gm. of protein per kilogram of body weight. A standard allowance of 1 gm. of protein per kilogram of body weight per day appears, therefore, to provide a margin of safety of from 50 to 100 per cent., as far as the requirements of adult maintenance are concerned. It is plainly desirable in all cases, that grain products be supplemented by milk products, and it is clear that in providing for needs of growing children and of pregnant or nursing mothers the proportion of milk in the diet should be more liberal than it need be when only maintenance is concerned; this both because of the superior amino-acid make-up of the milk proteins and to provide amply for the mineral elements and vitamins as well.

Frequency of Syphilis Especially in Railroad Employees.—A general medical examination of 1,763 patients of the Mayo Clinic showed that 3.1 per cent. had syphilitic infections obvious enough to be detected without the use of the routine Wassermann test. The lowness of these figures Stokes and Brehmer contend, reflects, to some extent, the weakness of clinical judgment in the recognition of this disease as compared with current figures based on the routine Wassermann test. Part of the lowness of these figures is attributable to the large farming element in the clientele of the clinic and to the low incidence of venereal diseases in the states from which most of the patients are drawn. Of the railroad employees examined, 11.7 per cent. had syphilis. The disease was eight times as frequent in them as in farmers (1.5 per cent.), three times as frequent in them as in business men (3.8 per cent.), and twice as frequent as in laborers (6.1 per cent.). The doubtful value of the history of the infection and the blood Wassermann test in the recognition of these cases is shown by the fact that 24 per cent. of the patients gave no history of infection other than gonorrhea; 62.5 per cent. had observed no secondary manifestations, and 53 per cent. were completely Wassermann negative on the blood. On the other hand, 64 per cent. of those whose spinal fluids were examined showed positive findings. Of the diagnoses, 58.7 per cent. were contributed by laboratory procedures; 41.3 per cent. were identified by routine physical examination. Of the men examined, 79.5 per cent. had syphilis of the nervous system; 18.7 per cent. had cardiovascular syphilis. Pupillary abnormalities, muscular paralyses and fundus changes were present in 62.5 per cent. of the cases. Of the persons examined, 65.1 per cent. showed abnormal knee reflexes, and similarly high percentages prevailed for the other simpler details of the neurologic examination. Definite mental symptoms were present in 38.4 per cent. These findings suggest that the routine railroad medical examination is insufficient to protect the public from the dangers of syphilis in men concerned in the operation of the trains. Three suggestions are made with a view to increasing the efficiency of the railroad medical examination, with respect to the recognition of syphilis: First, routine Wassermann tests should be performed on all employees between the ages of 17 and 25 by a competent state board of health laboratory, and repeated on all employees reaching 32 years of age. Second, there should be annual effective examination of men between the ages of 25 and 40, rather than of men over 50. Such examinations should include more attention to pupillary reactions than is at present given, and should employ those fundamentals of the neurologic examination, such as tests of the deep reflexes, Romberg, etc. These can readily be performed by competent general examiners. Third, formal educational propaganda should be undertaken by railroad medical departments for the education of medical examiners and employees alike to the great significance of syphilis in industrial insufficiency and personal ill health.

Journal of Medical Research, Boston

November, 1919, 41, No. 1

- *Studies on Rocky Mountain Spotted Fever. S. B. Wolbach, Boston.

Rocky Mountain Spotted Fever.—It is impossible to abstract briefly the results of the extensive and detailed study made by Wolbach. All phases of the subject are discussed. The conclusions as to the parasite itself are these: Three definite morphologic types of the spotted fever parasite can be recognized: (1) An extranuclear bacillus-like form without chromatoid granules, relatively large and only present in ticks during the initial multiplication of the parasites; (2) a relatively small rod-shaped form with chromatoid granules, probably the same form seen within nuclei in sections of ticks, and rarely in smooth muscle cells in the blood vessel of mammals; and (3) a relatively large lanceolate paired form present in ticks and in the blood and lesions in mammals. This lanceolate form is characterized by its "chromatoid" staining reaction, and according to the evidence at hand, is the form in which the virus is passed between the tick and mammalian hosts. The other two forms described are multiplicative stages, and can only be demonstrated occasionally and with difficulty in mammalian hosts. The name *Dermacentrolexenus rickettsi* is proposed by Wolbach for this parasite.

Operative Treatment of Seminal Vesiculitis.—Cunningham discusses the relationship between infections of the prostate and the seminal vesicles and arthritis, and the surgical treatment of these infections.

Etiology of Vesical Diverticulum.—In Hinman's opinion, vesical diverticulum is the result of anatomic, pathologic and mechanical factors in the vast majority, if not all, instances, and in this sense is always an acquired condition. A mild and chronic urinary obstruction, in association with the necessary anatomic or pathologic predisposing conditions of the bladder wall, is particularly conducive for the development of diverticula. Median bar formation is one of the most frequent types of obstruction.

Preserving and Increasing Therapeutic Efficiency of Cardiovascular Stimulants.—Zueblin urges that proper instruction of the wholesale and retail druggists ought to be encouraged on the subject of deterioration of chemicals and pharmaceutical preparations. In Zueblin's experience, fermentative processes in the organic drugs cannot be discarded entirely as a possible cause of these changes. Whenever possible, he says, use fresh drugs, freshly prepared, they will serve the purpose better for securing help and improvement to the patients. The old and shopworn preparations, after a more or less prolonged existence of oblivion in the drawers or in the form of old solutions, will be called on in vain to save a patient's life. In his experimental work, Zueblin incidentally detected a possibility of increasing the therapeutic efficiency and electric radiation of drugs by a short exposure of various remedies to the passage of electric waves. The practical methods of such a process are still a subject of studies and experimentation, but this much can be said, that the "life period" of the drugs can be raised to several months, and even years. Equally, there seems to exist a possibility of imparting new life to dead pharmaceutical preparations and compounds, and by doing so to restore and increase pharmacodynamic activity.

*Handshaking as Route of Infection. H. W. Hill, St. Paul.—p. 72.

Underlying Causes of Narcotic Habit.—These causes, Lambert says, must be sought for in the psychology of a personality unable or unwilling to face individual problems, difficulties, disappointments or defeats. In such cases an anodyne is demanded to bolster up the ego or to afford escape from painful experience. Solve the personal problem and the individual is freed from the need of narcotic forgetfulness.

Handshaking as Route of Infection.—The general conclusion of most practical observers has been that the route of hand infection is the great pathway of infection, and is responsible for perhaps 90 per cent. of all contact infection, medical or surgical, except the venereal diseases. While the handshake does not rank with kissing in directness, it is not confined, like kissing, to the exchange of nasal or oral discharges, but includes the discharges of the bowel and bladder. Moreover, the hands are so constantly infected and handshaking is so constantly repeated that, in the long run, Hill says, it probably eclipses the relatively less common and less promiscuous kissing in its sum total damage.

Sanitary Social Service.—With more syphilis now in this country than tuberculosis; with blind asylums filled with children as a result of gonorrhea; with women unsexed and their nervous systems shattered as the result of gonorrhea, usually contracted from their husbands; with paresis, which a hundred years ago was a medical curiosity but which is now filling insane hospitals with cases of locomotor ataxia and cerebrospinal syphilis, constituting a great part of the work of the modern neurologist, is it not time, asks Board, that the doctor, the lawyer, the minister, the teacher, the Women's Federation and the legislative bodies awake to the appalling facts of this situation and begin in a rational, thorough manner the eradication of venereal disease?

New Operation for Suspension of Uterus.—DuBose describes his method as follows: A linen or silk thread, on a full curved needle, is carried through the broad ligament as a running stitch, close to and immediately underneath the round ligament, beginning at the internal abdominal ring, carried across the fundus of the uterus, engaging superficially under the peritoneal coat, passing underneath the opposite round ligament until the other internal ring is reached. The needle is unthreaded and a ligature carrier is passed through the aponeurosis of the rectus muscle about one inch from the abdominal incision, and on a level with the internal abdominal ring, through the musculature of the anterior abdominal wall until it emerges from the parietal peritoneum at the internal abdominal ring. The linen suture is threaded on the carrier and drawn through the abdominal wall. The same technic is carried out on the opposite side. Then both ends of the thread are caught, and the uterus is pulled up into the desired position. Two hemostats are applied to the thread; one on either side, where it emerges from the aponeurosis of the rectus muscle. The peritoneum is then closed, the aponeurosis of the rectus muscle is sutured, and while the forceps are still in position, the linen suspension thread is tied. The placing of the forceps as described prevents the drawing too tightly on the suspension suture, which would bring the uterus too far forward, and possibly so narrow the space between the uterus and abdominal wall as to result in hernia or obstruction. The hemostats are removed after the tying of the suspension suture. The closure of the abdominal skin incision is then completed.

Forgetting: Psychologic Repression. A. Carver.—p. 46.

Surgical Aspect of Spinal Tumors.—Twenty-seven cases of true neoplasm of one sort or another, associated with cord symptoms, are analyzed by Sargent. Fifteen were cases of encapsulated intrathecal extramedullary tumors, all benign except one, a fibrosarcoma. In no case was the tumor situated above the fifth cervical or below the eleventh thoracic segment. The tumors were enucleated. Of these patients six are (or when last heard of were) doing their full ordinary work; one patient, 77 years of age, is in perfect health and vigor, and the other four are so far recovered that they may reasonably be regarded as successful cases. Of the four unsuccessful results, one (whose paralysis had existed for nine years before operation) remains virtually in statu quo, five and one half years after removal of the tumor. The remaining three patients died. In twelve of the twenty-seven cases the tumors were of a malignant character.

They were intrathecal extramedullary; intramedullary and extrathecal. In none of the twelve cases of malignant growth in this series was the exact nature of the case diagnosed before operation. The fact that the cord was being subjected to an increasing degree of compression led in each instance to the performance of an exploratory laminectomy, and in all but one the diagnosis of "tumor" was made before operation (one was thought to be a tuberculous caries); in all, too, the segmental level of the compression was correctly ascertained before operation. But in no instance could the exact position with relation to the cord and membranes, or the nature of the tumor be foretold. The operations were, therefore, primarily of an exploratory character. Two patients, one with a high cervical intramedullary tumor, and the other with a sarcoma of bone in the upper dorsal region, died within a few hours of the operation. Of the remaining ten patients, three were not benefited, seven were benefited to a variable degree. One patient lived seven years after operation and one lived six and one-half years after operation. Others were lost to further observation.

Autoserumtherapy in Meningitis.—Waterhouse's patient had cerebrospinal meningitis. The symptoms became aggravated and finally 20 c.c. of the patient's own blood serum were injected into the subarachnoid space by lumbar puncture after removal of the same quantity of cerebrospinal fluid. This procedure was repeated on the three following days with 12 c.c. of serum and on the fifth day 5 c.c. of serum were injected. Improvement set in from the time of the first injection and convalescence was rapid.

Acute Abdominal Cases.—Stretton reports a case of pedunculated polypoid adenoma attached to the posterior wall of the stomach about 1 inch inside the pyloric orifice. The tumor was removed. The patient made an uneventful recovery. A second case was one of large hemorrhage into the wall of the cecum between the muscular and mucous coats. The result was what appeared to be a large cyst. During the appendectomy which was performed at the same time, the cyst burst and nearly two pints of blood escaped. The cause of the hemorrhage is believed to have been a strain endured during the moving of some heavy objects. The third case was one of ovarian cyst which contained 6½ gallons of fluid.

Dublin Journal of Medical Science

December, 1919, No. 576

*Cause of Eclampsia. H. Tweedy.—p. 225.

*Case of Congenital Syphilis. J. Moore.—p. 229.

Cause of Eclampsia.—The basis of Tweedy's theory is that ordinary food becomes poisonous during pregnancy, and when in this condition it gives rise to toxemia and eclampsia.

Congenital Syphilis.—Moore cites the case of a girl, aged 12 years, the victim of congenital syphilis, who was treated successfully with Donovan's solution (liquoris arseni et hydrargyri iodidi, 8 c.c.; syrupi aromatici, 24 c.c.; aquae, 210 c.c.), one-half ounce, taken three times daily, after meals. He says "in these days of salvarsan, neo-salvarsan, khar-sivan, soamin, and other organic compounds too numerous to mention, and of the combined salvarsan and mercurial treatment of syphilis, we are perhaps too apt to forget older and no less effective means of combating and defeating the spirochete."

Influence of Edinburgh on M'Gill University. J. Meakins.—p. 5.

Binet Scale for the Blind. W. B. Drummond.—p. 16.

*Beri Beri Among Chinese in France. A. R. Leggate.—p. 32.

Beri Beri.—Two hundred and sixty-nine cases were observed by Leggate. Of these, 200 patients showed edema of the legs and body; forty-six of these showed no other

symptom. One hundred and eighty-three had loss of deep reflexes, and of these, seven had no other symptom. One hundred and fifty-five had paresthesia, nine of these without any other symptom. Inability to rise from a squatting position without the aid of the hands or other assistance was a striking symptom in some of the cases. In the dry type of case, it was the rule—66 per cent.; in the wet type, it was the exception—6.5 per cent. When the edema was marked, Leggate used purgatives. A saturated solution of magnesium sulphate, with 15 minims of dilute sulphuric acid to the ounce of solution, was his favorite. An important point in the treatment emphasized by him is to discontinue the polished rice diet and to administer eggs, beans, yeast and peas.

*Is Fat Starvation a Causal Factor in Production of Rickets? H. S. Hutchison.—p. 8.

Sores, Analogous to Veld Sores and Barcoo Rot, Appearing Among Soldiers Working in Blue Clay and in Chalk. D. D. Logao.—p. 13.

Prenatal Tuberculosis.—Allan defends the proposition that a child may be born tuberculous; in fact, he believes that antenatal tuberculosis is more common than is generally supposed.

Fat Starvation as Cause of Rickets.—Hutchison's observations lead him to the belief that in rickets there is no fat starvation, and that the excessive loss of calcium in this condition is not brought about through the agency of fat. This conclusion is supported by the fact that the average daily excretion of soaps in rickets was 2.2 gm., as compared with 2.5 gm. in health. Fat could only remove calcium as an insoluble soap, and as there is no increase in soaps in rickets, there is evidently no connection between the calcium loss in rickets and the fat excretion.

Feeding Infants on Dried Milk.—Borland suggests that it would be an infinitely better plan to feed a baby in relation to its weight than by calculating quantities of feeds according to age alone. This method has produced very satisfactory results in Willesden, where it has now been practiced for more than two years. The present scale is based chiefly on a full cream dried milk which has been modified to resemble human milk, but others not so modified have answered satisfactorily when given according to scale. The investigation was carried out primarily on sixty-nine babies of ages ranging from 3 weeks to 8½ months. The smallest feed which produced a satisfactory gain, the baby otherwise being in good health, was chosen from the clinic cards and noted. In this way 188 feeds at various weights were obtained. It has been Borland's practice to arrange breast feeding at intervals of three hours, three and one-half hours and four hours, according to the age of the child and the progress made. The four hourly intervals are begun as early as possible. In the case of the three hourly intervals the number of feeds given in the twenty-four hours is six, in three and one-half hourly intervals, and in four hourly intervals five feeds are given daily. It was found that by adding the number 9 to the weight, if below 7 pounds and the number 10 to the weight from 7 to 16 pounds, inclusive, the required number of level teaspoonfuls of dried milk to be given in twenty-four hours was obtained. Working tables are given.

Eliminating Alimentary Toxemia.—Assuming that a lactic acid fermentation in the large intestine is the condition to be aimed at in the control of an alimentary toxemia, Strode and Benjafield administer the carbohydrates in the form of coarse uncrushed oatmeal. This may be taken raw or cooked sufficiently to soften the outside of the grain, only leaving behind a hard core. The result is that the partially digested grain reaches the large intestine in the form of carbohydrate. The center of the grain is composed of unaltered starch, while the outer layers, which have been subjected to the digestive action of the juices of the mouth, stomach and small intestine, are composed of simpler molecules, the disaccharids and hexoses. Both these latter can rapidly be converted into lactic acid and carbon dioxide by a suitable bacterial flora. One of the authors has been combining this course of treatment with the ordinary symptomatic methods in his practice for the last fifteen years. Failures have been met with, but they have all been failures in that the lactic acid fermentation could not be obtained. In all cases where this fermentation has been established the condition of the patient has been materially improved. Cases are cited.

- *Treatment of Chronic Cases of Gas Poisoning by Continuous Oxygen Administration in Chambers. J. Barcroft and D. Dufton.—p. 179.
- Mustard Gas Poisoning. C. M. Wilson and J. M. Mackintosh.—p. 201.

Hematuria of Unusual Origin.—In the cases reported by Frankau, the onset was usually sudden, with fever rising to 100 or 102 F. The patient complained of pains in the shins and along the radial border of the forearms; headache was slight; there were often slight pains in the back. The respiratory, circulatory and alimentary systems showed only those changes which are common to all mild febrile diseases. In one case, the headache was so severe, and pain in the spine so marked, that meningitis could not be excluded on admission. A lumbar puncture was performed and a few drops of normal cerebrospinal fluid were collected; but in no other case were there symptoms or signs of any involvement of the nervous system. Sometimes, on the first day, invariably within a few days, there was marked hematuria; at the same time a slight dysuria was added to the other symptoms. In several cases it was the hematuria alone that led the patient to seek medical aid. After a few days, the hematuria disappeared, although, microscopically disintegrated red cells, pus cells and epithelial debris were still to be found in the urine. But the symptoms persisted, lumbar pain and dysuria became more prominent, and the shin pains were often sufficient to prevent sleep. A labial herpes was observed several times on about the fifth day. The initial temperature fell to normal, but rose again after, at most, a few days. Often there were sharp relapses, such as are commonly seen in cases of trench fever; in other cases the pyrexia developed into a hectic type, with morning remissions.

Action of Chlorin on Bronchi.—Generally, the results of experiments with chlorin showed that inhalation of 1:5,000 up to 1:1,000 produces an increased rate of respiration with a transient bronchoconstriction. This bronchoconstriction, Gunn believes, is produced reflexly by the first contact of the irritant vapor with the bronchial mucous membrane. It lasts such a short time that therapeutic measures to combat it would be unavailing. A subsequent sudden increase in the concentration of the gas produces thereafter an apparent slight and gradual bronchoconstriction, but from histologic observations it appears probable that this is due rather to edema of the bronchial mucous membrane than to contraction of the bronchial muscle.

Unilateral Alterations in Blood Pressure.—According to Cyriax, the differential blood pressure sign (differences

between the readings in the two arms) is nearly always present in unilateral or bilaterally unequal traumatism or operations. As regards the maximum pressures, differences of 10 mm. are found in about 83 per cent. and of 20 mm. or over in about 12 per cent. of all cases. As regards the minimum pressures, similar differences are found respectively in 81 per cent. and 20 per cent.

Treatment of Chronic Cases of Gas Poisoning.—Twenty-six patients were treated by the continuous administration of oxygen. The patients were placed in chambers in which the percentage of oxygen aimed at, and usually maintained, was between 40 and 50. The usual term of residence was five days, sixteen or seventeen hours of each day being spent in the chambers. The night was always spent in them. The effect on the red cell count was as follows: if the red cell count was markedly higher than 5 millions, it was reduced by residence in oxygen, usually to just about that figure; if the red count, as was often the case, especially with mustard gas, was not raised above 5 millions, residence in oxygen did not alter it. The subsequent history of cases differs: in some the red count tends to rise, in others it remains nearly normal at the end of two and one-half months. As the red count fell, there was usually a fall—but a much slighter one—in the hemoglobin. The color index, therefore, rose. An almost constant sign in the gassed cases studied has been a failure on the part of the pulse to return normally after exercise to its resting rate. This condition has been benefited by the oxygen treatment in nearly all cases; and in about half it was brought to—or almost to—the normal condition. Of fourteen patients treated, six suffered from nocturnal attacks of dyspnea. None of these had attacks in the chamber; three appeared to be cured permanently, and two others were permanently benefited. The patients all stated that they were able to walk faster and with less distress than before the treatment. In the second series of cases a definite test for dyspnea was introduced, in which the opinion of the patients was not involved. Of the six patients thoroughly tested, four increased the quantity of work which they could do with a given degree of breathlessness by over 20 per cent. and two others by over 10 per cent.

- *Alcoholism and the Thyroid. Le Clerc.—p. 394.
- *Treatment of Vincent's Angina. Capitan.—p. 396.
- *Hospital Ships. Chevalier.—p. 399.
- Dual Nature of Farcy. G. Chénier.—p. 403.

Alcoholism and Thyroid Agnesia.—Le Clerc reports three cases of defective development of the thyroid in children of drinking fathers. One patient was a man of 30 with myxedema, one a girl of 14, a mongolian imbecile, and the third a child with myxedema. The older children in the families seemed to have escaped the taint, but the younger ones all showed the effect of it more or less. He has never encountered any other cases of thyroid agnesia.

Treatment of Vincent's Angina.—Capitan has treated 200 cases of Vincent's angina with intramuscular injection of 6 c.c. colloidal arsenic, and states that it never failed to sterilize the lesions in twenty-four or forty-eight hours, and the cure was complete in four or five days. A second injection was only exceptionally required. Local treatment is not absolutely necessary.

Hospital Ships.—Chevalier is inspector general of the medical department of the navy, and he here describes the work of the various hospital ships bringing the wounded and sick from Flanders and Serbia and from the Mediterranean fronts. He urges that in building vessels for the merchant marine some should be designed so they could be rapidly transformed into hospital ships at need, the hospital equipment kept in readiness at some convenient point. (See also Paris Letter, p. 189.)

Dec. 23, 1919, 82, No. 41

*Food Value of Different Grains. C. Achard and L. Gaillard.—p. 500.

*Prophylaxis of Bovine Tuberculosis. J. Lignières.—p. 505.

Tincture of Box in Intermittent Fevers. S. A. de Vevey.—p. 508.

Value of Flours.—Achard reports that to the usual food of rabbits were added 50 gm. of different kinds of flour. Six sets of five rabbits each were thus fed separately on wheat, rye, barley, corn or rice flour over long periods. No difference in weight was apparent in any of the sets fed on different flours and no difference in the mineral content of the bones. The only practical conclusion from the research is that the mineral content of the food does not decide the mineral content of the organs and skeleton. The ash was as large in the animals fed on rice as with any of the other flours, although rice has less than a third as much mineral elements as barley and rye.

Prophylaxis of Bovine Tuberculosis.—Lignières would sweep away all indemnities, etc., for tuberculous cattle, and place the loss squarely on the shoulders of the proprietor. This, he declares, is the only effectual way to stamp out bovine tuberculosis by making the loss from it so excessive that the proprietors will be forced to take steps to protect their herds against it. According to the present measures, the proprietors have comparatively little personal interest in stamping out the infection. When they find that unless they do this their losses will be excessive, a new order of things will be inaugurated. Three things are necessary for this: (1) The nullification of the sale of any animal found to be tuberculous. The animal to be returned immediately to the vendor; the latter to pay the expenses of transportation and refund the purchase money; (2) The public health service to investigate the herd from which the tuberculous animal came, and brand all tuberculous cattle found destined for any purpose except slaughtering. The vendor to stand the partial or total loss when meat is confiscated on account of tuberculous lesions. (3) No indemnity to be paid to the owner of the cattle except when an animal is ordered to be slaughtered on account of tuberculosis of the mammary glands, or when a mistake has been made in the diagnosis.

With these regulations in force, he states, the tuberculous animal would have to be kept at home, and hence could not start new foci. It would have very little commercial value, as it could not be sold for anything except butchering, and not even for this if the disease is far advanced. The financial loss would be so great that the proprietors would spare no pains to protect themselves. This would transfer the fight against bovine tuberculosis from the authorities to private interests, instead of the latter hampering and seeking to circumvent the authorities in the task. The proprietor would not have to make any declaration, and would not be molested by any one so long as he kept his tuberculous cattle at home. He can call on authorities to help him weed out the tuberculous animals, and these he can keep separate from the others and send to the slaughter-house at his convenience as the years pass, while the rest of his herd is kept safe from infection with tuberculosis. He can take his own time and means to eradicate tuberculosis from his herd; and none of his tuberculous cattle need be branded if he does not attempt to sell them for any purpose except butchering. This prophylaxis based on private interests will act everywhere throughout the country at once, and will be kept up until bovine tuberculosis has disappeared. Lignières urges legislators to pass a law nullifying the sale of a tuberculous animal for any purpose except butchering, and providing for branding as described above.

*Ligation of Carotid for Traumatic Exophthalmos. A. de Lapersonne and Sendral.—p. 515.

*Hospital Hygiene and Influenza. A. Lesage.—p. 522.

Malaria and Dysentery Carriers Among the Demobilized. F. Barbary.—p. 524.

Ligation of Carotid for Traumatic Exophthalmos.—Slight exophthalmos was evident two days after the railroad accident fracturing the base of the skull, and neuromyotonic keratitis, ptosis, and intolerable subjective disturbances were

combated by de Lapersonne with ligation of the carotid. The thrill and murmur disappeared but the subjective chug-chug persisted, and the left common carotid was ligated likewise after having been prepared by several weeks of training of the vertebral arteries to prepare them to substitute the ligated artery. For this the carotid was cautiously compressed with the fingers. At first this induced dizziness, jerking, and profound asthenia for several hours, but finally it could be borne for ten minutes at a time, so that a ligature was thrown around the left common carotid also, eight months after the accident and five months after the first ligation. For the first three days there was a feeling as of ice in the head, but all the symptoms soon became attenuated, and the young man was much pleased with the outcome. Twenty-two months later, he still has frequent headaches but is able to read and write without difficulty. Bending over brings on severe dizziness. This symptom is marked in another case of ligation of both carotids. Both of the men are satisfied with their physical condition but complain of impairment of the memory and early mental fatigue. The right exophthalmos in another man had developed seven months after a war wound, and at the twenty-third month had suddenly become aggravated, threatening the loss of the eye. Ligation of the right carotid put an end to all disturbances at once and permanently.

Hospital Hygiene.—Lesage cites experiences—especially with influenza—which confirm anew that individual isolation is the base of all hygiene in hospitals.

Journal de Médecine de Bordeaux

Dec. 25, 1919, 90, No. 24

Substitution, Compensation and Vicarious Action in the Symptomatology after Injury of Nerves. A. Pitres.—p. 535. Conc'n.

*Reverdin Skin Flaps. W. Dubreuilh.—p. 545.

Technic for Reverdin Skin Flaps.—Instead of using a razor, as for Thiersch flaps, Dubreuilh lifts up the skin with a curved needle held at a right angle in hemostatic forceps, with the tip curving up. He pricks the skin with this tip, and as the skin is thus lifted up he cuts out the lifted up portion with a sharp bistoury. The needle thus has a small disk of skin impaled on its tip and this disk is transferred to the defect to be covered. By this means quite a large defect can be rapidly covered with forty or fifty of these disks, about 2 mm. in diameter; larger than this it is hard to detach the scrap, and smaller than this the scrap may be lost when cut out. No anesthesia is necessary, the patient feels merely the prick of the needle. He applies the grafts about 4 or 8 mm. apart, and takes them from nearby. When all are in place, he covers the surface with numbers of small pieces of gauze, a few centimeters wide, placed individually, watering with artificial serum, and presses them down with his hand. The gauze dressing is changed in forty-eight hours but the lowest layer of gauze can be left untouched, watering copiously with physiologic serum. The flaps take hold by the sixth or seventh day. They heal as cicatricial tissue, with the danger of retraction, but they accomplish the healing in cases in which otherwise it would take much longer or be impossible. These minute flaps can be taken so easily and leave such insignificant gaps in the skin that, even if the procedure fails, not much harm has been done. In one case a roentgen dermatitis on the back, as large as a plate, had shown no tendency to heal during the year, but applying these needle grafts, to the more favorable points in turn, led to the complete healing of the lesion in two months. The lesion seems to feel a stimulating action from the grafts even at points where the latter do not touch.

Smallpox in France. M. Guilhaud.—p. 162.

Polyvalent Lipovaccine Against Typhoid. A. Sezary.—p. 164.

Recent Progress in Infectious Diseases.—Tanon specifies among other progress the knowledge of the complications of typhus, and the favorable results reported by a few workers with serotherapy. Among them are Nicolle and Blaizot with an antiserum from horses that had been injected with emulsions of spleen and suprarenals from inoculated guinea-pigs. Monvoisin during his war imprisonment treated typhus by intravenous injection of 1 or 2 c.c. of convalescents' serum. In his experience this reduced the mortality from 30 to 10.34 per cent. The best results were obtained with blood drawn the eighth day. The injections seemed harmless, and could be repeated if necessary. Lebaillly and Poisson arrested an incipient epidemic by inoculating the thirty-four contacts by injecting subcutaneously 1 c.c. of horse serum or convalescent's serum, and 1 c.c. of serum from a guinea-pig developing the disease.

Peritonitis in Typhoid.—Rathery refers to peritonitis from propagation without perforation, and reiterates that the slightest suggestion of peritonitis calls for complete immobilization, with ice to large areas of the abdomen, and absolute fasting; nothing should be allowed except subcutaneous injections of artificial serum. The slightest movement should be forbidden, and the chilling of the abdomen should be extensive and constant.

Treatment of Diphtheria Bacilli Carriers.—Arloing expatiates on the effectual sterilization of the throat realized with insufflation of desiccated bactericidal antiserum prepared by injecting the horse simultaneously with diphtheric toxin and the bodies of the bacilli. The desiccated antitoxin is mixed with an inert powder and with gum tragacanth to make it adhere to the tissues. These insufflations are given three or four times a day, between meals, after gargling with an antiseptic solution. The nozzles of the atomizer are interchangeable and individual. In three weeks, and sometimes earlier, the diphtheria bacilli disappeared from the throat. He insists that this treatment is absolutely harmless and rapidly effectual. It is important to examine for bacilli anew a week after they have apparently permanently disappeared, as it is possible that they have been merely temporarily checked in their development. Stevenin comments on the misleading conclusions liable from the intermittency of positive findings in the smears. He has had good results recently with insufflation of desiccated *sérum antimicrobien*, insufflated three or four times a day in the pharynx and nasal fossae. Labbé and Canat have also reported good results with it.

The Gonococcus Count as Guide to Treatment.—Ramond reports the differential count of the cells and cocci in the urethral secretions from nine patients repeatedly examined. Nothing was found to throw light on the prognosis or treatment except that the gonococcus curve seems to indicate a partial local immunization in the course of the third week. This suggests that it might be well to wait for the end of the third week before giving balsamics. At this time they might usefully supplement the partial immunization going on, and thus get a chance for effectual action.

*Present Status of Our Knowledge of Ferments. H. Roger.—p. 741.

*Fracture of the Malleolus. E. Juvara (Bucharest).—p. 743.

*Diabetes Insipidus and Its Pituitary Origin. P. Pagniez.—p. 746.

The Ferments.—In this opening lecture of his course on experimental and comparative pathology Roger reviews the data accumulated in respect to ferments, and suggests that further study of those that preside over reductions and oxidations may explain the origin of many pathologic conditions and the mechanism of death.

Reconstruction of Fractured Malleolus.—Juvara gives illustrations showing the technic for osteosynthesis with fracture of the malleolus. The reconstruction of the bone in its normal outline is accomplished by driving a long, slender nail from below, slanting upward, far into the bone to hold the parts in normal apposition. Or two nails may be driven in close together, the tips diverging a little. One set of

roentgenograms shows nails driven into both malleoli the fourth day after the fracture. The nails were pulled out the twenty-second day, and the cure was complete the thirtieth. In another case illustrated the nail was driven through the skin into the internal malleolus two days after the fracture, and it had healed completely by the twenty-fourth day. Both these patients were men. In other cases he drove two nails horizontally through the malleolus into the tibia, or axially into the fibula from below, or else merely tied a wire around the fractured bone after fitting the parts into place. One illustration shows the foot like a big pin-cushion with three nails thus driven into the bone. No immobilizing apparatus is required and the foot can be moved from the second day, and this should be done as much as possible thereafter. The disappearance of the pain is the result accomplished first by the osteosynthesis. The first dressing is changed the second or third day as blood oozes from the nail holes. The secret of success is to reconstruct the bone in this way at once, as an actual emergency operation, immediately after the fracture. This prevents swelling of the region, and the pains disappear after the osteosynthesis. He uses ordinary iron nails, 1 mm. in diameter and 7 or 8 cm. long. The spongy bone of the malleolus takes the nails easily. Sometimes nailing the internal malleolus in this way is sufficient to hold the external in place without further intervention. The internal malleolus is exposed by a U incision, the base above, and the flap is turned back on the leg. The internal saphenous vein skirts the anterior margin of the malleolus and injury of this must be guarded against.

Pituitary Diabetes.—Pagniez analyzes five recent works on this subject published in Spain, Italy, France and this country. Many points are still obscure, he remarks, but two things seem to be certain, namely, that pituitary treatment has an immediate and specific inhibiting action on essential polyuria in man, and that any traumatic irritation of the nerve regions adjacent to the pituitary entails polyuria. In pituitary treatment we have now a remedy of considerable efficacy for the polyuria of diabetes insipidus, although its action is transient.

*Gas Cysts in the Abdomen. M. Letulle.—p. 781.

*Peripheral Vasoconstriction in Shock. R. Ducastring.—p. 782.

*Cultivation of Malaria Hematozoon. M. Chambelland.—p. 783.

*Acute Appendicitis. C. Lenormant.—p. 784.

Gas Cysts of Intestine and Peritoneum.—Letulle concludes his illustrated description of intra-abdominal pneumatosis by stating that it is a complication of chronic obliterating lymphangitis, and that a laparotomy may lead to resorption of the gas and total subsidence of all the cysts. This has occurred repeatedly when compression of stomach or bowel by some cyst had made a laparotomy imperative.

Peripheral Vasoconstriction in Shock.—Among other arguments in favor of peripheral vasoconstriction as an important factor in shock, Ducastring cites two cases of shock in which the slow, weak or absolutely imperceptible pulse became normal under the action of amyl nitrite.

*Facial Diplegia. A. de Castro (Rio de Janeiro).—p. 801.

*Bernard-Horner Syndrome from Shell Shock. Léry and Thiers.—p. 808.

*Reflex Adduction of Eyeball. Id.—p. 810.

*Stunted Pyramidal-Cerebellar System. D. E. Paulian (Bucharest).—p. 815.

*Extraction of Bullet in Lateral Ventricle. G. L. Regard.—p. 818.

*Hypertrophic Neuritis. M. Dide and Courjon.—p. 825.

*Achondroplasia in Greek Art. A. Porot.—p. 833.

Facial Diplegia.—De Castro remarks that in his service at Rio a large number of cases of facial diplegia are encountered every year. The paralysis is rapidly progressive, and it may take days or months for it to subside. It may subside completely on one side while persisting on the other. When accompanying polyneuritis, the facial paralysis usually is bilateral and persists longest. Contracture is rare and seldom affects both sides. A series of illustrations are given of three typical cases.

Reflex Adduction of Eyeball.—Léri and Thiers give illustrations of a case in which any peripheral stimulus, such as touching the mucosa of the ear with cold water, or tickling the mucosa of the nose, induces at once a pronounced deviation inward of the eyeball on that side. This phenomenon was marked in two patients with other symptoms indicating injury of the labyrinth, and was negative in twenty-two other neurologic patients. It may possibly aid in detecting an upset in the muscle balance from excessive functioning of the third pair and weakness in its physiologic antagonists, the abductors or sympathetic.

Defective Development of Pyramidal-Cerebellar System.—A woman of 31 and her brother, 26, both present evidence of arrested development of the pyramidal system and afferent cerebellar tracts. The disturbances from this cause did not become apparent until about the age of 20 in each. There was a history of spinal cord disease in an uncle, and the mother had unmistakable signs of syphilis. The cases resemble those published as cerebellar ataxia, but Paulian prefers to label them familial pyramido-cerebellar dysgenesis, emphasizing also the inherited taint.

Extraction of Bullet in Lateral Ventricle.—Regard says that the rarity of the localization of the bullet in the lateral cerebral ventricle and its curious mobility are not so interesting in this case as the primary displacement of the projectile, the means taken to complete the diagnosis, and the successful extraction. The bullet entered at the posterior-inferior end of the left second parietal convolution but there was no word blindness, which tends to disprove the location of this special center at this point. The bullet probably did not land in the ventricle but was pushed into it by the strange expulsive force exerted by the brain tissue for foreign bodies partially embedded in it. Intense headache, somnolency and mental confusion were the symptoms, none pathognomonic, but roentgen examination with the head in different positions showed a displacement of 6 cm. of the bullet. It was easily extracted from the rear after it had been made to drop into the occipital extension of the ventricle and a large flap had been cut in the skull. The whole procedure proved so simple and easy that Regard says he would feel justified in attempting it in cases of apoplexy when hemorrhage into the ventricle is threatening to prove fatal. It could be done at one sitting, but he did not complete the operation till the following day as he wished to be certain of his asepsis.

Hypertrophic Neuritis in Adults.—Dide and Courjon report five cases with illustrations. The extreme atrophy of muscles began in the hands and arms in five personal cases and in four published by Long and by Hoffmann. In thirteen known cases no inherited or familial taint was discoverable. In ten cases the onset was between 30 and 40. The disease in adults may assume various types, and complicating cerebellar symptoms are rare.

Achondroplasia in Greek Art.—Porot relates that after the siege of Athens by the Romans, 86 B. C., some of the ships taking the loot from Athens to Rome were wrecked, and one of these wrecked ships was discovered a few years ago in the sand bars off Tunis. Its cargo of Greek statues, etc., is now installed in the museum at Bardo. Among them are some bronze statuettes of dwarfs which show all the attributes of the achondroplastic type described by Marie. The trunk, the head and the sexual organs in this type develop normally, but the long bones are stunted, and these features are faithfully reproduced in these dancing figures of which illustrations are given.

*Effect of Pyelitis in Infancy on Kidneys Later in Life. E. Rhonheimer.—p. 1929.

*Functional Capacity of Tendon Sutures. J. Dubs.—p. 1938.
Venereal Disease in Swiss Army. W. R. Schnyder.—p. 1952. Cont'd.

Prognosis of Pyelitis in Infants for Later Life.—Rhonheimer has secured information in regard to the later life in 122 cases of pyelonephritis in infants. The diagnosis cannot be positive without examination of the urine, but the experiences related show that the urine may show pathologic

findings for months and even for more than a year when the child seems otherwise to have entirely recovered. His examination from one to eight years later demonstrated entirely normal conditions in the urine; no recurrence during the interim was known in any instance. This complete healing of the pyelitis in infants is in direct contrast to what is observed with pyelitis in older children. In the latter, recurrence is so common that some clinicians consider the pyelitis of pregnancy merely the flaring up of the disease dating from childhood. He reviews the testimony of pediatricists, including Birk's case in which pyelitis at 9 was followed by grave recurrence at 11, but the urine and kidneys seemed to be normal throughout a pregnancy at 18. In Rhonheimer's 122 cases, about 23 per cent. were boys, and necropsy showed severe changes in the kidneys and only slight lesions in the bladder. This testifies that infection is blood-borne in infants, while in older children it is usually ascending infection. After infancy, fully 90 per cent. of pyelitis patients are females.

Functional Prognosis of Tendon Sutures.—It has generally been assumed that sutured tendons behave normally thereafter, but Dubs, in a personal experience with 100 cases and analysis of 375 cases on record of injury of tendons in the arm requiring suture, has found that the ultimate outcome is far from favorable. In over 43 per cent. the cause of the interference with function was adhesion to surrounding tissues; infection and suppuration were responsible only in 11.3 per cent. The outcome was poorest in the cases in which secondary suture had been done, and best when the suturing was done early. Even with primary suture, the outcome was bad in 50 per cent. of the extensor tendons and in 10 per cent. of the flexors. The earlier the suture the less danger of adhesions forming. The surgeon should make every effort to ward off adhesions, as the free play of the tendon is indispensable for proper functioning. Too little attention has been paid to this point hitherto.

Policlinico, Rome

November 1919, 23, Medical Section No. 11

*Hemolytic Splenomegaly. P. Biffis.—p. 393; Idem. Livio Losio.—p. 410.
*Pernicious Anemia. F. Marcora.—p. 424.

Hemolytic Splenomegaly.—Biffis reports eight cases of familial chronic jaundice with enlargement of the spleen, but no bile pigments in the urine. The jaundice did not manifest itself until between 22 and 25. The cases were all in several generations in one family. The children present all the symptoms except the jaundice; this will probably appear as they grow up. Removal of the spleen is always followed by improvement, but the abnormal fragility of the blood corpuscles persists unmodified. Only one case is known (Micheli) in which the corpuscles regained normal stability, but even in this case, reexamination several years later showed that the fragility of the corpuscles had returned. The jaundice is no index of the gravity of the condition. In the familial or congenital form, the jaundice is usually pronounced, while the other symptoms are often mild and there is little or no anemia. Biffis and Ceconi have previously published seven cases of the acquired type, and have recently encountered the familial cases here described and another set in a second family. The urobilinuria, attacks of pain in the right hypochondrium and paroxysmal intensity of the jaundice, which had begun at 25, all pointed to the acquired type in the case first seen, but investigation revealed seven other cases in the man's family tree, including his two children.

Splenectomy for Hemolytic Jaundice.—Losio reports a case of chronic hemolytic jaundice in a woman of 22 whose splenomegaly was first noted at the age of 12. He removed the spleen at 22, and the disease seemed to be cured for a time, but then all the symptoms gradually returned. The vessels in the spleen showed peculiar complex changes for which he knows of no precedent; among the other changes was a tendency to calcification of the middle coat. He remarks in conclusion that not only is there no criterion to distinguish the acquired from the congenital type but, in

some cases, it may be impossible to distinguish between primary and secondary jaundice.

Pernicious Anemia and Typhoid.—Marcora gives the minute clinical and necropsy details in a case of progressive pernicious anemia in which typhoid bacilli were found in the blood marrow and spleen, although there was nothing in the findings elsewhere or in the antecedents to suggest typhoid infection. The grave anemia had developed insidiously in the course of three or four months, with urobilinuria, and death about the sixth month. A colored plate shows the blood findings.

Modern Technics for Transfusion of Blood. A. Sebastiani.—p. 369.

*Pathology of Sweat Glands. G. L. Colombo.—p. 383.

Necrosis of Clavicle.—The girl of 7 was scratched in the back of the right hand by the nail of another child in play, and a furuncle developed, with secondary rapidly acute staphylococcus osteomyelitis of the clavicle, compelling its entire removal eight days after the primary scratch.

Sarcoma in Frontal Sinus.—Caliceti illustrates a case of rapidly growing primary sarcoma originating in the frontal sinns in a soldier. As long as the growth was restricted to the sinns it caused absolutely no symptoms. When these appeared the growth was already inoperable. If discovered or suspected in an early stage, it might be well to try an autovaccine, as Citelli recommends. Caliceti obtained most gratifying results with an autovaccine in a case of sarcoma of the upper jaw. He reviews the literature on malignant disease of the frontal sinns.

Changes in Sweat Glands.—Colombo found severe changes in the sweat glands in patients with nephritis, also in tuberculosis and in various chronic intoxications. The elimination of toxins through the sweat glands entails these changes in time, and he induced them in cats and rats by blocking kidney functioning.

*Serotherapy of Anemia. Sylvio Prado Pastana.—p. 623.

*Treatment of Fractures. Alípio Santos.—p. 666.

Serotherapy in Anemia.—Prado Pastana says that with the Besredka technic it is a simple matter to obtain an anti-human hemolysis serum from rabbits. This hemolytic serum, as he calls it, has a potent stimulating action on the blood-producing centers. The blood corpuscles are produced in larger numbers, comparatively, than the hemoglobin. The hemoglobin takes a longer time to approximate normal, and it is wise to aid this with iron. The principal indication for this treatment is severe aplastic anemias, especially when the blood-producing centers seem exhausted and a stimulant is called for. The immediate effect surpasses that from administration of iron. The best results are observed with minute and well spaced doses; 1 c.c. of the 1:20 antiserum is the preferred dose, diluted with 9 c.c. of physiologic solution, and infused into a vein, very slowly after the first. None of the five patients whose cases are described with minute detail complained of the technic, and no trace of anaphylaxis was ever noticed. The intervals were from eight to twelve days, and only two or three injections were made.

Treatment of Fractures.—Alípio Santos describes the first case in Brazil treated by what he calls the Anglo-American method, that is, weight extension applied to the suspended limb. He extols the perfect healing and functional outcome.

*Pleurisy with Heart Disease. Luna Freire.—p. 353. Begun in No. 43, p. 337.

Epidemic Poliomyelitis in Uruguay. V. Escardó y Anaya.—p. 356. Cont'n. See abstract below.

Pleurisy with Heart Disease.—Luna Freire has recently encountered three cases of pleural effusion in the left side in persons with heart disease. Analysis of these cases and of the literature shows that the heart disease with arterial lesions and with pleural effusion on the left side originates in the aorta, and spreads secondarily to the myocardium. This suggests that syphilis may be the primary factor. The symptoms are the same whatever the origin of the pleurisy, but few think of testing for syphilis, and yet this might give the clue for effectual treatment. In his three cases chronic aortitis was evident, and one of the men, a physician, succumbed to the progress of the disease, with multiple hemorrhages, epistaxis, hematemesis and melena. In all, the heart was displaced toward the right of the sternum. He discusses the reasons why the effusion is generally on the right side with heart disease, while in his three cases the left side only was involved. In Beaufumé's sixteen cases, only one involved the left side. The mechanical factors explain the predilection of congestion and edema for the right side, but do not explain the pleurisy; infection is required for this. The term arterial cardiopathy should be restricted to the cases in which chronic inflammation of the large vessels of the base spreads to invade the myocardium or the valves, and syphilis is generally responsible for the inflammation of these large vessels. This conception allows a more favorable prognosis.

*Hemiplegia Consecutive to Influenza. F. Abente Hacdo.—p. 771.

*Epidemic Poliomyelitis in Uruguay. V. Escardó y Anaya.—p. 779.

*Connection Between Syphilis and Tuberculosis. E. Mariño and J. C. Mussio Fournier.—p. 807. In French.

Comparative Analysis of French and German Arspbenamin. A. Prunell.—p. 812.

Hemiplegia After Influenza.—Abente's patient is a young man who for a few weeks after influenza presented symptoms of the Millard-Gubler type of hemiplegia. By exclusion, Abente accepts an infectious arteritis of influenzal origin as probably responsible for the hemiplegia.

Epidemic Poliomyelitis in Uruguay.—Escardó's address on this subject was presented at the recent International Child Congress. He comments in particular on the element of pain which was a feature of the disease during the three epidemics in Uruguay; 1906, 1912 and 1916. He mentions further two unpublished cases of cephaloplegia, like those described by Figueiras at Rio de Janeiro. The two cases were seen ten years ago by de Pena at Montevideo. Probably unrecognized poliomyelitis was responsible for the cephaloplegia. The child was totally unable to hold up its head, and there was also a slight tendency to paralysis. These symptoms subsided in about a week in one case, but the infant of 2 years succumbed to asphyxia. Escardó adds that serotherapy is being tried at Buenos Aires in poliomyelitis, and the results are quite encouraging.

Syphilis and Tuberculosis.—Summarized on page 359 when published elsewhere.

*Hemostasis with Prostatectomy. A. Freudenberg.—p. 967.

What the War Has Taught Us About Nutrition. K. Bornstein.—p. 968

Local Use of Calcium Chlorid for the Prevention of Serious Hemorrhages in Suprapubic Prostatectomy.—After or during suprapubic prostatectomy one of the chief dangers, Freudenberg has found, lies in the serious hemorrhages that

so frequently prove fatal. He has, however, of late been using a method of prevention that he finds very satisfactory, namely, the local application of a 6 per cent. solution of calcium chlorid. From ten to twenty minutes before the operation, 100 c.c. of the solution are injected into the patient's bladder, the contents of which have been removed by catheter. Immediately before the skin incision is made, the fluid is withdrawn from the bladder and air is injected. After the enucleation of the prostate, for which the smallest possible incision in the bladder is made, the resulting cavity is plugged tight with medicated gauze that has been immersed in the calcium chlorid solution. Above this a large-sized drain is inserted. The balance of the cavity of the bladder is likewise plugged with the gauze dipped in the calcium chlorid solution. Through the Freyer drain a Nélaton catheter may be inserted and the greater part of the urine drawn off through a tube, thus preventing to a great extent the infiltration of urine into the tissues. The abdominal flaps are then sutured above and below close up to the drain. Following Freyer's technic, the bladder itself is not sutured. After twenty-four hours, the Freyer drain is removed; also the tampon in the upper part of the bladder. The tampon in the prostate cavity is not removed for two or three days. Caution then is necessary, and it may be advisable to use hydrogen dioxide to avoid hemorrhage from mechanical irritation. For bladder lavage during the first few days following the operation, calcium chlorid should be added by way of precaution. Freudenberg has operated in twenty-six cases in this manner without experiencing any serious difficulties from hemorrhages.

Radical Nonoperative Cure of Hemorrhoids.—After twenty years' experience in treating hemorrhoids, Boas finds injections of 96 per cent. alcohol the most effectual measure. For years he had used injections of phenol (Kelsey's method) with fair success, but the results were often not entirely satisfactory. Recurrences were rather frequent. The main objections to phenol are its escharotic and toxic effects. Boas sought for an injecting medium that was free from these objections, and for four years has been using 96 per cent. alcohol with eminent satisfaction. He describes his method under three headings: (1) preparation of the patient; (2) the treatment proper, and (3) after-treatment. The patient must remain in bed during the treatment. Boas objects to the ambulant treatment of hemorrhoid patients which he thinks, if he is correctly informed, is all too prevalent in America. By means of the Bier suction glass the hemorrhoids are drawn out of the anus. From experience one learns how long and how vigorously the suction must be applied in order to bring forth all the hemorrhoids, for it is essential in this method that every nodule should be injected. When the operator has thus informed himself as to the number and size of the hemorrhoidal tumors, they are returned within the rectum. If the hemorrhoids bleed too freely it is well to control the hemorrhage by repeated injections of calcium chlorid. On the first day the patient is given a purge. After securing a thorough evacuation, the bowel is cleansed the next day by means of a soapsuds enema. The treatment proper begins with the patient in the knee-chest position. With the Bier suction glass, the hemorrhoidal tumors are now brought well into view. With a record syringe of 10 c.c. capacity, from 2 to 5 c.c. of 96 per cent. alcohol are injected, carefully but quickly, deep into the hemorrhoids. In one of moderate size 2 c.c. may be

injected in the upper half and 2 c.c. in the lower half. In an especially large tumor, 5 c.c. may be required. The whole procedure takes only two or three minutes even when the vascular tumors are numerous. Occasionally the injections are painful and he now uses a local anesthetic from fifteen to twenty minutes before applying the treatment. A slight burning sensation may be felt for a time, but there should be ordinarily no further discomfort. After the injections the hemorrhoidal mass should, if at all possible, be returned to the bowel. If the mass is large, this may entail some difficulty. In rare cases it may be necessary to leave a small part of the mass outside of the rectum, but this only delays the cure a few days, as through gradual necrobiosis the extra-anal portion will slough off. The after-treatment is important. The patient remains in bed for four days in the dorsal recumbent position and receives during that period only a liquid diet, in order to reduce intestinal activity to the minimum. On the fourth or fifth day a purgative is given. If prolapse of the injected piles does not occur during the first stool, it will not usually occur at all, so that the patient can then be allowed to resume a normal diet and will soon be able to move about freely. The final test, applied about a week after the injection, consists in using the Bier suction glass again to see if the hemorrhoids are now securely anchored within the rectum. Boas has treated fifty-two patients by this method. A radical cure was effected in all the cases and there have been no recurrences as yet, although in two cases a second injection became necessary. The total amount of alcohol injected never exceeded 10 c.c.

Regenerative Processes in Blood Vessels.—As regards transplantation of blood vessels, Bier believes that autoplasmic transplants are the only ones that can be counted on. Various investigators had maintained that homoplastic and heteroplastic transplants, or even segments of dead blood vessels, would live and conduct the blood stream. But the microscope has shown that such transplants suffer the same fate as all other homoplastic and heteroplastic transplants: they disintegrate and are absorbed, while other surrounding tissues, usually scar tissue, take their place. Bier adds that the remarkable part of it is that even this scar tissue may actually perform the needed function. For a more extended treatment of this question, Bier refers to the investigations of Borst and Enderlen published in the *Deutsche Zeitschrift für Chirurgie* 99, June, 1909.

Meaning of the Term "Uremia."—The current views in regard to the pathogenesis of uremia are only approximately correct and need revision, Veil thinks. The term "uremia" covers too many things that in the light of recent investigations are not closely associated. If for traditional reasons the term must be retained, it should be used, he says, to designate "only azotemia or ureahemia." Its diagnosis should be based on the chemical proof of abnormal quantities of the constituents of the urine and of nitrogenous bodies in the blood.

Bone Disease from Undernutrition.—Böhme says that the similarity between the clinical picture of osteomalacic affections and that of ordinary rickets led to the use of the same therapy, which proved adequate; namely, highly nutritious diet that was sufficiently varied, prevention of unnecessary weight bearing by the bones and administration of cod liver oil with phosphorus. This therapy usually produced an improvement in the general condition, a rapid remission of the pain and the return of strength, so that the patient was soon able to walk and later to go about his work. In deformities of the legs, corrective bandages worn during the night were found beneficial. The fact that the same external conditions sometimes produce rickets tarda and sometimes osteomalacia raises the question as to the relation between the two diseases. The pathologists support the view that from an anatomic standpoint the two diseases cannot be differentiated. Clinicians insist on a differentiation, especially from the pathogenetic standpoint, maintaining that in osteomalacia a hyperfunction of the ovaries is a main cause. Böhme thinks that the observations of the war period bring out also the close clinical relationship between the two diseases.

The bone changes in rickets and in osteomalacia are essentially the same. In respect to localization, however, there is some difference, which may perhaps be explained by the modifying influence of the ovaries. The symptoms and clinical course of this war period type of osteomalacia differ from those of peace times. That the glands of internal secretion were often damaged could be concluded from the fact that certain secondary sexual characteristics were repressed.

Injury of the Middle Meningeal Artery.—The diagnosis of injury of the middle meningeal artery, while an easy matter in typical cases, becomes exceedingly difficult if the classical symptoms of cerebral pressure are absent or are obscured. Salomon gives as convincing evidence of the difficulty attending the diagnosis of epidural hematomas the fact, as cited by Brun, that of thirty-nine cases of hematoma in Krönlein's service at Zurich only nineteen were diagnosed before the death of the patients, and thus could be given operative treatment. To add to the difficulties, patients are often admitted to the hospital in an unconscious state, nothing of their past history being known, while the brain is completely paralyzed. Salomon thinks a more widespread knowledge of atypical lesions of the middle meningeal artery would lead to better results. The diagnosis and the indications for operation should not be allowed to depend so exclusively on the classical symptoms of pressure on the brain. Though aphasia may be the only focal symptom, this alone may at times be taken as an indication for operation. If after two or three days' observation, in spite of temporary improvement, the typical brain pressure pulse, the aphasia and the mental condition remain the same, we are justified in assuming the presence of a good-sized, unabsorbable extravasation of blood, the removal of which is clearly indicated. Salomon is convinced that extension of the operative indications will reduce quite perceptibly the number of cases that come to necropsy, which now amount to about 50 per cent. of all cases.

Quincke's Edema.—Sieben reports a case of influenza in a 13 year old girl which was followed by chorea and a concurrent angioneurotic edema. He has observed a number of cases, in which not only chorea but also other nervous diseases were associated with influenza, so that he does not hesitate to count the chorea and edema among the after-effects of influenza. Furthermore, he reports as after-effects of influenza: serious maniacal emotional conditions, and even genuine mania of the severest type, necessitating confinement of the patient in an asylum but with final complete recovery. If Quincke's edema follows one infectious disease (influenza), it may possibly follow other infectious diseases. If there are no intestinal symptoms that point to the origin of the disease, it would be well to look for some infection that may have played an important part in its genesis.

Gonococcus Otitis in Infants.—Putzig reports a case of purulent otitis media in a 14 month old child which occurred nearly two months after the child had been successfully treated for a typical gonorrhea. He thinks that it was due to a second infection transmitted from the mother who was still suffering from a specific gonorrheal discharge. He emphasizes the need of bacteriologic examination of the discharge in all cases of persistent suppuration of the ear in infants, especially those who have had gonococcus infection, as knowledge of the gonorrheal origin makes possible specific treatment, such as with 1 per cent. protargol solution and, if necessary, potassium permanganate lavages, which usually bring about a cure in a few days. If a bacteriologic examination is not made, the child may be seriously injured by a protracted otitis, and through lack of knowledge of the danger, other members of the family may become infected.

Poisoning by Oil of Eucalyptus.—Auerbach reports a case of poisoning in a man of 47 who had ingested about 20 c.c. of oil of eucalyptus. Half an hour afterward he was found unconscious in bed. Auerbach found the patient cyanotic; with a weak, slightly accelerated pulse, and covered with a cold sweat. The pupils were contracted and fixed. The area of cardiac dullness was increased, and breathing was shallow. Ingestion of milk caused vomiting, and milk lavage brought

forth distinct evidence of eucalyptus oil. The condition of the patient slowly improved, and complete recovery followed on the fourth day. Auerbach gives this account of the case because he finds in the literature few reports of poisoning from oil of eucalyptus.

*Actinomycosis of Lung. G. H. Moll van Charante.—p. 1150.

*Growth of Urinary Calculi. F. Hijmans.—p. 1159.

*Case of Ascending Paralysis. A. Q. van Braam Houckgeest.—p. 1163.

*Present Status of Acute Purulent Pleurisy. W. F. Wassink.—p. 1165.

Actinomycosis of the Lung.—Moll van Charante reports the case of a man of 45 with a history and aspect suggesting tuberculosis, but a very tender point was found in the inter-scapular space, with dullness, and the vocal fremitus was weak, and there were some râles. Roentgenoscopy revealed what seemed to be periostitis of ribs, but the discovery of actinomycetes in the sputum cleared up the diagnosis. Necropsy showed symmetrical abnormal conditions in the periosteum of nearly all the ribs, the periosteum often sagging like a bag, and the lungs were studded with minute lumps. In a second case pain in the left side for three months was finally explained by a swelling assumed to be a tuberculous process in a rib. The infiltration was hard as wood but soon softened, and an incision released pus containing the actinomycetes. Symptoms suggesting pleurisy with effusion developed, back of the process in the chest wall. No fungi were found in the sputum and the lung did not seem to be involved. Complete recovery followed ample incisions, roentgen treatment, potassium iodid and copper sulphate, locally and internally. Agglutination may help in the diagnosis; the actinomycetes does not become agglutinated but the patients' serum is said to agglutinate *Sporotrichum beurmanni*, although Harbitz and Israel were unable to confirm this. After long coughing and expectorating, sudden violent pain in side and chest is soon accompanied by the hard infiltration, with final softening and retraction of the chest wall. With secondary infection, air from the lung may get into the abscess and the succussion sounds then are pathognomonic. One case is on record of ten years' duration, but others are known with a fatal outcome in three months. Potassium iodid, eucalyptus oil and roentgen treatment have not benefited more than a few cases. Illich found no recoveries in fifty-eight cases, but Mayer found seven in thirty-five, and Netter has reported a case of complete recovery in four weeks under 6 gm. daily of sodium iodid. Two cases are on record of recovery under vaccine therapy when conditions seemed very grave, seventeen injections in one case and six in the other. Operative intervention as for cancer has now a record saving twelve otherwise doomed patients.

Growth of Urinary Calculi.—In one of Hijmans' two cases, 11 large stones, weighing altogether 110 gm., were found in the bladder six years after cystotomy to clear the bladder of 2 small stones. In a second case, two years after pyelotomy 6 phosphate stones were found in the kidney pelvis, weighing in all 40 gm. Such cases teach the necessity for keeping patients under surveillance after an operation for urinary calculi, and regulating their habits to correspond to the urine findings. Regular supervision at three months' intervals might reduce materially the number of cases of recurring urinary calculi.

Acute Purulent Pleurisy.—Wassink analyzes recent literature on this subject, and remarks that the trend seems to be to restrict intervention to puncture in recent cases of rapid onset with numerous cocci in the empyema or serous effusion. The puncture may be supplemented or not with insufflation of gas. If the condition of the lung permits, Mzingo's method of closed sterilization may be tried and may ward off actual empyema (THE JOURNAL, Dec. 21, 1918, p. 2062). The Dakin method is still on trial, and should not be attempted outside of a large hospital. The experiences with open treatment of empyema in young children have been extremely unfavorable. Repeated puncture seems to be all the intervention that should be attempted in infants.

PHYSICAL AND HYGIENIC BENEFITS OF MILITARY TRAINING AS DEM- ONSTRATED BY THE WAR

MERRITTE W. IRELAND, M.D.

Surgeon-General, U. S. Army

WASHINGTON, D. C.

Probably no other class of men have the vision, as medical men have, to see the good that would result from universal military training.

There never has been a real survey of the man power of the United States, but all of us know that many surprising facts would be developed if such a survey were made. The Civil War gave a certain indefinite survey at that time, but during the last fifty-five years tremendous changes have taken place in our mode of living, and the human mechanism has not adjusted itself to the changes of civilization. We have had no opportunity to judge the defects among our male population. For a long time the finger of scorn has been pointed at the Army and Navy because we had such a high percentage of venereal disease. I have been interested in this subject for a quarter of a century. The only reason we had a high percentage of venereal disease was that we knew the amount of this disease among our soldiers and sailors and published it to the world. We always knew that the rate of venereal disease did not represent the rate in the Army but did represent, to a fair degree, the rate in the civil population in the vicinity of our military posts. We do not contract venereal disease in the Army to any extent, but acquire it almost exclusively from without the military reservation. With a distinct understanding of the meagerness of the information we had at the beginning of the world war, it is most interesting to review the statistics furnished by the draft, the report covering the mobilization of nearly 5,000,000 men in the military forces of the United States (Army, Navy and Marines).

BENEFITS RESULTING FROM THE WAR

The cessation of hostilities at a period in the war when the American battle casualties had been insignificant, in comparison with the losses of other belligerent countries, offers a favorable opportunity to consider the brighter side of the war and to estimate what benefits have accrued to the nation as a whole, and to the individual soldier in particular, from calling to the colors approximately one twentieth of the entire population of the United States. These benefits are manifold and may thus be roughly classified:

1. Improvement in physical development as a result of outdoor life, good food, regular exercise and strenuous physical training.

Alertness, activity, strength, endurance and discipline, combined with a body free from disease, are the first requirements of a soldier. These qualities are largely obtained by gradual and well regulated physical training. As applied to the recruit, this training enables him to bear the hardships and to overcome the difficulties of warfare. The beneficial results of physical exercise during the training are supplemented by the outdoor life, the regular hours required, the plain, simple food, the good sanitary surroundings, and the many other features that promote the development of a high type of physical manhood. The improvement in the physical development of the young man in the Army was most striking. Our sanitary inspectors visited dozens of camps to investigate the thoroughness of the examination made on the arrival of the recruit at camp, and they made the same investigation of the soldier before his demobilization. At the first of these examinations, the inspector was greatly impressed by the stream of naked men who were awkward, narrow chested, with flabby muscles and often with a stoop. Contrasted with this picture, he was tremendously impressed by a similar line of naked men who presented themselves for examination before demobilization. They were bronzed, erect, broad-chested soldiers with fine muscular development and a characteristically alert and self-confident air. Many exaggerated statements have been made as to the gain in weight soldiers have acquired during the war. Some day these statistics will be available, but at the present time no correct statement can be made. The officer in charge of the sanitary division of the Surgeon-General's Office estimates that the average gain in weight in the first year of military service is from 15 to 20 pounds. The actual records of one company of National Guard troops under the semitropical conditions existing on the Mexican border in 1916 showed an average gain of 12½ pounds a man in nine months. Studies on this subject during the war made by the division of foods and nutrition in the office of the Surgeon-General showed in one infantry company an average gain of 10 pounds a man after four months of service, and in three artillery batteries an average gain of 6¼ pounds in six months. Another study showed 2½ pounds gained in five weeks. There is no doubt that this gain in the soldiers' weight was almost entirely muscular tissue. It is reasonable to believe that a six months' training of the youths of our land during the year they are 19 years of age would produce similar good results from the physical standpoint.

2. Detection and cure of many obscure and latent pathologic conditions, particularly hookworm, malaria, venereal disease, tuberculosis and focal infection.

The examination of a young man for universal training would bring similar results. Many of the disabili-

ties detected would not be disqualifying for military service, but could be remedied during the period of training. Notable examples would be: painful feet, weak backs, hookworm infestation, malarial infection, venereal disease, and focal infection from diseased tonsils and diseased teeth. In the examination of the draft it was ascertained that 29 per cent. of the men had physical disabilities that were disabling for military service. A small list is given in the accompanying table. Suffice it to say, however, that of the 225,000 cases of venereal disease in the Army during the war, prior to May 1, 1919, 200,000 were contracted before enlistment, that is, before the men joined the Army. This statement was made from incomplete statistics and is only relatively correct.

SOME IMPORTANT DEFECTS REVEALED BY THE DRAFT

	Per Cent.
1. Defects of feet (flatfoot, 11 per cent.).....	13
2. Venereal diseases:	
During first period of draft.....	2.9
In later period of the draft.....	5.7 8.6
(Increase due to improvement in method of examination and tabulation, and also to the larger percentage of negroes inducted during the later period.)	
3. Hernia and enlarged inguinal rings.....	4
4. Defective vision (largely refractive errors).....	3½
5. Defective physical development (including underweight and underheight).....	3½
6. Organic diseases of the heart.....	3
7. Deformities or loss of extremities.....	3
8. Tuberculosis.....	2.50
9. Hypertrophy of tonsils.....	2½
10. Defective and deficient teeth.....	1½
11. Mental deficiency.....	1.25
12. Otitis media (purulent).....	1
13. Hemorrhoids, varicocele, varicose veins (combined).....	1
14. Goiter (simple and exophthalmic).....	0.75
15. Deformities of hand.....	0.75
16. Cardiac arrhythmias and tachycardia.....	0.50
17. Asthma.....	0.25

3. A determination by examination of the actual physical condition of the adult male population of military age, and a consequent awakening of the nation to the necessity for efforts directed toward limiting the possibility for the continued evolution of physically defective citizens.

The examination of the registrants before Dec. 15, 1917, resulted in the rejection of 29 per cent. This was before the industrial and economic classification of all registrants had been made. After this classification had been accomplished, 14.5 per cent. were rejected by the local boards, and approximately 7 per cent. were rejected by the boards at military camps. This gives a total rejection by camps and local boards of 21.2 per cent. Forty-seven per cent. of the men examined were found to have certain defects. Fifty-three per cent. were accepted as fully meeting the physical standard, with no defects recorded.

4. Instruction in sanitation and personal hygiene gained by both precept and practice in camp. A great part of this acquired knowledge the discharged soldier will take back to his home and transmit to his family and fellow citizens.

As you know, a great effort was made at our concentration camps to provide every requisite for high-grade sanitation. Camps were models of cleanliness. An ample supply of potable water was furnished; shower baths were unlimited; sewage disposal was complete, and the best of food was provided. Every effort was made to have food properly prepared. The men were protected against flies and mosquitoes. Food handlers were examined to detect possible carriers of typhoid, paratyphoid and dysentery. Modern laundries were established. Vice and liquor selling were abolished or limited. In addition to what the soldier saw of sanitary methods at the camp, he was given instruction in sani-

tation and personal hygiene; he was provided with suitably fitting shoes, his teeth were examined and put in condition, and he was vaccinated against typhoid, paratyphoid and smallpox. He was frequently examined to detect incipient disease. A great part of this knowledge the soldier retained to take back with him into civil life. It will have a marked influence on his method of living, and he will transmit a part of his knowledge of hygiene to his family and neighbors.

5. Education in sex relation and in the matter of protection from the dangers of illicit sexual indulgence. This subject is of so great importance that it is given a special heading.

There is no one thing which demands greater attention from the people of the United States than does the widespread prevalence of venereal disease. The discussion of this subject has been tabued in polite society until quite recently. The examination of the men between 21 and 31 years of age developed the fact that more than 5 per cent. were suffering from manifest venereal troubles. The Wassermann test was not taken, so cases of syphilis which did not present local manifestations were not detected. The wide prevalence of venereal disease among our young men was a revelation to the people at home and I think that from now on the campaign against venereal disease will be one of the good results from the war. While the soldier was in camp he was protected in every conceivable way from venereal disease—by education, by law-enforcement, and by early treatment. The low record for venereal disease in the American Army in France was a revelation to our allies. It is believed that the education on this one subject alone will be of tremendous value to the country in the future.

6. Training in discipline and the development in the soldier of respect for authority.

Among those promoted to commissioned and non-commissioned grades, there was developed the faculty to command and exact obedience. I do not think too much importance can be laid on this subhead. I am certain it is accepted by all that in recent years the tendency of the American youth has been in the direction of disrespect for authority, whether parental, municipal or national. I think the discipline of military life has had a most wholesome effect on the American soldier, and will in a marked degree make him better material for citizenship. The experience which these men gained will be of inestimable value in civil life.

7. Protection, by vaccination, of 5,000,000 men against the danger of contracting typhoid, paratyphoid and smallpox for several years to come.

This will have a far-reaching effect on the population of the United States for many years. We have learned to control typhoid fever and have practically eliminated by sanitary measures dysentery and malaria. Even as late as the Spanish-American War, typhoid fever, dysentery and malaria filled our hospitals. During the world war those three diseases were practically negligible quantities in our sick report. Until May 1, 1919, we had only 213 deaths from typhoid fever, thirteen deaths from malaria, and forty-two from dysentery. Think of the great change that has taken place in this respect as contrasted with the Civil War and the Spanish-American War.

BENEFITS OF UNIVERSAL MILITARY TRAINING

The statements that I have made refer to the good the Army did the American soldier during the world

war. There is every reason why this good could be multiplied with the youth of the land by universal military training. It would give us a wonderful opportunity to make a physical survey each year of the youth of the land. It would enable us to detect physical disabilities that could be remedied and would make the man economically more valuable for the rest of his life. Many of the disabilities which men carry through life and which interfere with their value as citizens are remediable. At one time during the war, 10,000 cases of hernia were awaiting operation. All of these disabilities could be corrected during the period of military training. Defective vision could be corrected; men with weak feet and weak backs could be relieved. The mental defectives could be classified; the young man would be given an object lesson in discipline and be taught respect for authority—the good that could be accomplished is unlimited.

PATHOLOGIC ANATOMY OF TRAUMATIC FRACTURES OF CRANIAL BONES

AND CONCOMITANT BRAIN INJURIES *

E. R. LeCOUNT, M.D.

AND

CARL W. APFELBACH

CHICAGO

This attempt to consider the injuries of the brain and cranial bones when the latter are broken by external violence is based on conditions encountered in 504 postmortem examinations made by one of us during the years 1911 to 1918. It does not include all the postmortem examinations during that period of the bodies of persons with such traumatic fractures, for in about sixty instances the measurements and other steps necessary in the interests of precision were not so detailed as in the 504 here reviewed. The patients were cared for in the Cook County Hospital or the Hospital of the House of Correction, and some postmortem examinations were of bodies of persons who were found dead or who died en route to a hospital.

SIX FUNDAMENTAL CONSIDERATIONS

Notwithstanding certain still mooted questions regarding the mechanism whereby the injuries of both the cranial bones and the brain are produced, and especially the influence a whirling motion of the falling head and body may have on the characteristics of the injuries, there are six facts that are generally accepted and need brief mention as a background for what follows:

1. There are six regions where the greater thickness of the cranial bones forms arches thicker below and gradually thinning out in the vault: one in front from the root of the nose and glabella; one behind, including the inion and the external and internal crests of the occipital bone, as well as the torcular eminence; one on each side from the external angular processes of the frontal bone and prolonged obliquely back and into the body of the sphenoid in the bones of the skull base, and finally one on each side formed by the petrous bones and continued externally in the protuberance of the mastoid (Figs. 1, 2 and 3).

2. With violence applied to the cranium, these arches hinder horizontal bending; whereas the bone between the arches can more easily bend vertically. As a result, the bone between

the arches flattens the more in a horizontal plane and breaks across, the linear fractures radiating up into the vault and down into the bones of the base of the cranium between the arches.

3. With the head in motion, the brain lags behind the more rapidly moving cranium, and as a consequence is closer to the cranial bones *opposite* where violence is applied; and with the axis of the skull abruptly shortened at right angles to where violence is applied, the brain is the more bruised opposite that place.

4. The resistance (weight) of the trunk and extremities transmitted to the skull via the condyles of the occipital bone tends to bend in the bottom of the skull, especially the arches, and is one factor determining the course and distribution of the fractures.

5. When the cranial bones are broken with the head in a fixed position, contrecoup bruising of the brain is reduced to the minimum and the bruises are direct, at the place of fracturing.

6. The general direction taken by fractures which course between the arches is also well known, and is shown in Figures 4, 5, 7, 10, 19, 23 and 29.¹

NATURE AND LOCATION OF FRACTURES

About 85 per cent. of the 504 cases here considered were simple linear fractures or linear fractures with branches; in the remainder, the bones were extensively comminuted and with some of the fragments depressed. With the bones of the cranial base involved slightly more than those of the vault, both were involved in varying degrees in all but about 8 per cent. of the 504. When grouped according to the fossae chiefly involved, with one group for the vault and one for fractures so extensive that several fossae and part of the vault as well were broken, the incidence is as shown in the accompanying table. In this table are

LOCATION OF FRACTURES

	Pos- terior Fos- sae	Mid- dle Fos- sae	An- terior Fos- sae	Vault	Ex- ten- sive	Totals
Total number.....	178	166	61	49	50	504
Some depression.....	6	11	6	4	7	34

Short falls	36	43	9	2	2	92
Longer falls	48	37	13	16	13	127
Street car	17	12	16	4	13	62
Automobile and autotruck..	11	17	7	2	11	48
Assault	18	15	6	9	3	51
Meningitis	15	7	13	3	1	39
Healed fractures	7	6	4	1	0	18
Decompression operation....	15	27	3	8	6	59

included a few fractures partly healed or so healed that their courses could still be followed. Many of the fractures of the back fossae ran forward to end in the ethmoid bone or one of the foraminae of the middle fossae. Violence for these fractures as indicated by the scalp injuries was usually to the back of the head. Of the sixty-one fractures of the anterior fossae, seventeen were simple linear, from 2 to 5 cm. long and in the roof of one orbit. Of the extensive fractures, usually with comminution, the violence was to the back of the head for twenty-seven, to the side for nineteen and in front for four. The average of the total linear length of these fractures was 70 cm., the greatest 138.9 cm. (Fig. 19). With the vault fractures, some traumatic diastasis of sutures was not rare: in twelve of the forty-nine, part of the sagittal or its entire length was affected; in three, the coronal

*From the Coroner's Medical Service at the Cook County Hospital.

*Aided by a grant from the Otho S. A. Sprague Memorial Institute.

1. We have made no attempt to cite from the literature, but wish to refer especially to the work of Tilmann (Arch. f. klin. Chir. 66:750, 1902; 59:236, 1899) and that of M. Auvray (Maladies du crâne et de l'encéphale, Paris, 1909).

suture, and in five, one or both lambdoid sutures. As regards the meningitis, the petrous parts of the temporal bones were the portal of entry for the infection in twenty-three, the ethmoid bone in thirteen; in two fractures the opened sagittal suture with the scalp laceration, and in one the petrous bone of one side was

Fig. 1.—Location of the reinforcing arches of the cranium.

Fig. 2.—The thickest portions of the cranial bones are in the shaded areas.

broken and a decompression operation had been made. With thirteen of the eighteen fractures with some degree of healing, there were contrecoup bruises, and in four, direct bruises alone. With one of these healed fractures there was an abscess of the left cerebral hemisphere in front, the fracture of the right posterior fossa and no outside bruise of the brain; in other words, the abscess opposite the fracture.

CONCOMITANT BRAIN INJURY

The injuries of the brain concomitant with fractures of the cranial bones are preponderantly of the outside of the brain, owing partly to the inbending of the cranial bones, but chiefly to the bumping of the brain against the cranial bones. Most fractures of the cranium result from causes which first set the head into rapid motion and then suddenly stop the skull against a firm object. The brain, floating as it does in the cerebrospinal fluid, lags in the movement of the head, so much so that when the head stops moving the brain receives its greatest injury by bumping against the cranial bones directly opposite where the cranium is broken. When the bones of the temporal fossae or of the nuchal planes of the occipital bones are fractured, because of their thinness, there is frequently a bruise directly under the fracture resulting from inbending of the bone and compression of the brain. The back half of the cerebrum is larger and heavier than the front half, and because of this the front poles of the cerebrum are more frequently and more extensively bruised than the back poles. If the lateral ventricles are enlarged (internal hydrocephalus) the sides of the brain and front poles are more easily torn. As a result of these factors the frontal and temporal lobes are the most frequent site of injury; injuries of the back of the head have a large percentage of contrecoup bruises; of the sides, the next largest percentage of contrecoup bruises; and injuries of the front are more frequently associated with large direct bruises than with large contrecoup bruises.

DEGREES OF BRAIN INJURY

That the degree of brain injuries may be indicated in some way, they are roughly divided into seven groups, according to severity:

1. Severe lacerations of the brain from 4 to 6 cm. in diameter and extending into the brain 4 or 5 cm. Here there is a defect in the surface filled with clotted blood and torn brain tissue. There were fifty-four injuries of this type, and in fifteen the tear had extended into one of the lateral ventricles (Figs. 14 and 22). In thirty-nine of the fifty-four, bleeding continued intracerebrally for a few centimeters, so that in places on some of the surfaces made by coronal sections of the brain beyond the margins of the bruises of the outside there were hemorrhages inside of the brain not connected with the surface (Figs. 12, 13 and 14). Thirty-six of the latter occurred in the frontal or temporal lobes, three in the occipital lobes, usually with severe injuries (street car, automobile, high falls, etc.). There were subdural hemorrhages with all fifty-four injuries, weighing from 10 to 220 gm. All except eight were contrecoup injuries.

2. Bruises of the brain, usually wedge-shaped, in which the brain is infiltrated with blood from 2 to 4 cm. deep in a place 4 or 5 cm. in the largest outside dimensions (Figs. 25, 30 and 32). The leptomeninges covering the bruise are usually torn, the brain is lacerated from 1 to 2 cm. deep, the adjacent tissue is thickly infiltrated with blood, and the margins are edematous and dotted with petechial hemorrhages. Subdural hemorrhage is always present, but in amounts varying from a few grams up to 100 gm. Bruises of this type were the most frequent of all of the larger bruises. There were 248 in this series: 182 contrecoup and sixty-six direct.

3. Bruises, frequently with the leptomeninges intact, from 1 to 1.5 cm. deep, with little laceration of the brain tissue. There is generally hemorrhage into the brain, wedge-shaped on cross-section (Figs. 11, 16, 24, 25, 27 and 28). These are found with cranial fractures in which the trauma is usually of such a degree as might result from a short fall on a side-

Fig. 3.—As the arches come together at the body of the sphenoid bone they are curled up at their ends; because of this, fractures radiating down into the base of the cranium course toward the body of the sphenoid bone, as shown in many of the illustrations.

Fig. 4.—The fractures shown in this illustration and in Figures 5, 6 and 7 may be taken as "composites," that is to say, they represent conditions with extension from the vault down into the different fossae. (Figures 1, 3, 4, 5, 6 and 7 are taken from LeDentu, A., and Delbet, Pierre: Nouveau traité de chirurgie, XIII. Auvray, M.: Maladies du crâne et de l'encéphale, Paris, 1909.)

walk, floor, etc. They are also frequently associated with the severe injuries, mentioned above, that is, with a blow on the back of the head on the right side the large bruise will be of the left frontal or temporal lobe, while one of these more superficial bruises will be found of the right frontal and

temporal lobes or of the right side of the cerebellum (Figs. 11, 24 and 25). This type of injury was present with about 35 per cent. of all the fractures. In only fifteen when these were the largest bruises present were there subdural hemorrhages with clots weighing more than 10 gm., and in only two did they weigh as much as 90 gm.

4. Superficial contusions represented by closely set petechial hemorrhages of the cortex in places from 1 to 1.5 cm. in diameter (Figs. 21, 24, 27 and 32). The meninges are intact and usually there is a little bleeding into the leptomeninges about the contusion. One or more of these contusions is usually present when the brain is severely injured, oftentimes five or six. Like those in Class 3, they are in those parts of the brain some distance away from the direct line of force (Figs. 16, 21 and 24). Some of them were the only gross evidence of direct injury of the brain.

5. Hemorrhages into the pons and medulla, chiefly the pons, centrally located, often multiple and the individual hemorrhages from 1 to 3 mm. in diameter (Fig. 18). These are usually contrecoup in location, that is to say, the fractures do not course through the bones adjacent to the brain-stem. The explanation of these hemorrhages is variously stated: contrecoup bruising, stretching of the brain away from the brain-stem because the former is more movable, and interference with the blood supply of the pons and medulla (infarction).²

Fig. 5.—Composite fracture.

Fig. 6.—Composite fracture.

Fig. 7.—Composite fracture.

There were eighteen brains with hemorrhages in the brain-stem with fractures of the posterior fossae: in thirteen multiple, and in five a single hemorrhage from 2 to 4 mm. in diameter. In thirteen of the 166 fractures of the middle fossae, there were hemorrhages in the pons; ten of these patients lived less than one day, one three days, one seven days and one ten days. There were three with fractures of the frontal fossae, and all were associated with extensive injury of the brain. There were brain-stem hemorrhages in eighteen of the fifty extensively comminuted fractures; twelve with the violence applied behind, five of the side and one of the front of the skull. In the forty-nine fractures of the vault, there were hemorrhages in the brain-stem in five, and none of these patients lived longer than one day in the hospital.³

6. Small intracerebral hemorrhages, usually in the cerebral basal ganglia, from 5 to 10 mm. in diameter. There were only six of these in the 504 fractures of this series (Fig. 18).

7. Small intracerebral hemorrhages about 1 cm. in diameter, usually single, occurring when an extradural blood clot compresses one of the hemispheres. They are always in the compressed hemisphere. They were present with only four of the 104 large extradural hemorrhages (Fig. 30).

INCIDENCE AND NATURE OF BRAIN INJURIES

Brain Injuries with Fractures of the Posterior Fossae.—In 149 (83.70 per cent.) of the 178 fractures, the largest bruise of the brain was contrecoup, in sixteen (8.98 per cent.) direct; and in three both the contrecoup and direct bruises were of equal extent. In the remaining ten the brain injury was slight. When the fracture was near the midline, the bruising was usually fairly symmetrical of each frontal lobe at the tips, lower outer margins and of the tips of the temporal lobes (Figs. 20, 21 and 22). With the fractures coursing more outward from the midline and forward in the posterior fossae, the contrecoup bruises were chiefly of the opposite side of the brain (Figs. 10, 11, 12 and 13). As a rule with the violence applied close to the back of the ear, the frontal and temporal lobes on that side were little if any bruised. In 159 of this 178 (89.32 per cent.), one or both frontal lobes bore bruises, tears or both; in 120 (67.41 per cent.), the temporal lobes had so suffered; in sixteen (8.98 per cent.), the occipital lobes; and in fifty-five (30.89 per cent.), the cerebellum. As already

stated, the injuries of the frontal and temporal lobes were chiefly of their frontmost convolutions, undersurfaces and lower convolutions; but with the point of injury high on the back of the head, the undersurfaces of these parts of the cerebrum were chiefly bruised; with the injury at the level of the external occipital protuberance, the contrecoup bruises were chiefly of the frontal poles of the cerebrum; if at some distance from the midline, the outer margins of the opposite frontal or temporal lobes were chiefly bruised; in short, there has not been observed any noteworthy deviation from the directly opposite location of the contrecoup bruising of the brain which is such a conspicuous and important feature of the lesions accompanying the fractures.

Brain Injuries with Fractures of the Middle Fossae.—In 103 (62.04 per cent.) of the 166 fractures, the largest bruises of the brain were contrecoup, in forty-three (25.90 per cent.) direct. In the remaining twenty the brain injury grossly visible was only slight leptomeningeal hemorrhage of about equal extent on the two sides of the brain, except in a few brains which were without gross injury. In seventy (42.16 per cent.) of this 166, one or both frontal lobes bore bruises, tears or both; in 146 (87.94 per cent.), one

2. Greenacre, Phyllis: Multiple Spontaneous Intracerebral Hemorrhages, a Contribution to the Pathology of Apoplexy. Bull. Johns Hopkins Hosp. 28: 312, 1917.

3. With some of these hemorrhages, sugar is found in the urine, as it is also with large spontaneous (apoplexy) hemorrhages in the pons.

or both temporal lobes; in thirty-eight (22.89 per cent.), the parietal lobes; in fifteen (9.03 per cent.), the occipital lobes, and in ten (6.02 per cent.), the cerebellum. The bruises of the frontal lobes were mostly of the outer margin and undersurface. In only a few instances were the bruises of the frontal lobes deep, and then the external injury was of the back half of the parietal region of the opposite side. The bruises of the temporal lobes were preeminently of the outer margin

Fig. 8 (Case 23).—An extensive, traumatic, comminuted fracture of the cranial bones with an independent fracture of the roof of the right orbit. The fracture is 53 cm. long. The scalp was bruised opposite the right mastoid region. This man, aged 52, was struck by a street car six hours before death.

Fig. 9 (Case 23).—Extensive traumatic leptomeningeal hemorrhage due to extension from contrecoup bruises of the frontal and left temporal lobes.

and undersurface, depending on whether the violence was applied low or high on the vault, respectively (Figs. 23, 24, 26 and 27). One or both of the temporal lobes were bruised whenever the brain was injured.

Bruises of the Brain with Fractures of the Frontal Fossae.—In thirty-five (57.37 per cent.) of the sixty-one, the greatest bruising of the brain was direct, in thirteen (21.31 per cent.) contrecoup. In forty-four (72.13 per cent.), the frontal lobes were bruised or torn; in seventeen (27.70 per cent.), one or both temporal lobes; in three (4.91 per cent.), one or both parietal lobes; in nineteen (31.14 per cent.), one or both occipital lobes; and in eleven (18.03 per cent.), the cerebellum. In thirteen brains there was no gross evidence of injury, and in thirty-seven of

brain in thirty-one (62 per cent.) of the fifty was contrecoup; in fourteen (28 per cent.), direct; and in five, both the contrecoup and direct bruises were equally severe. In only two of the fifty brains were the injuries slight, consisting of direct leptomeningeal hemorrhage. The point of external violence was used in deciding whether the bruising was contrecoup or direct, because some of the fractures encircled the skull, and especially through the middle fossae. In thirty-nine of the fifty (78 per cent.), one or both frontal lobes were bruised or torn; in thirty-seven (74 per cent.), one or both temporal lobes; in seven (14 per cent.), one or both parietal lobes; in eight (16 per cent.), one or both occipital lobes; and in sixteen (32 per cent.), the cerebellum. Of the twenty-seven fractures in which the violence was applied behind, the contrecoup bruising was greatest in fourteen; in four, direct; in eight, chiefly contrecoup, but the direct bruises were also large, and in one there was

little injury of the brain. Of the nineteen with the violence applied to the side of the skull, in nine the contrecoup bruising was greatest, in five, direct, and in five chiefly contrecoup; but the direct bruises were also large. With the external violence applied in front, the direct bruises were greatest in three of the four, and in one the brain injury was slight.

Brain Injuries with Fractures of the Vault.—In thirty-nine (79.59 per cent.), the greatest bruising was contrecoup; in nine (18.36 per cent.), direct; and in one, the brain injury was slight. In eight of the thirty-nine brains, the contrecoup bruising was only slightly greater than the direct. The frontal lobes were bruised or

Fig. 10 (Case 24).—Typical linear fracture of the right posterior fossa resulting from the patient's falling backward and striking the back of the head on a cement floor. The patient was a white man, aged 45.

Fig. 11 (Case 24).—The location of the contrecoup tears of the left frontal and temporal lobes (Class 1), the superficial contusion of the right frontal lobe (Class 3) and the extent of traumatic leptomeningeal hemorrhage. The front half of the left cerebral hemisphere was covered by a subdural clot, and at the tears the clot was from 8 to 10 mm. thick. Altogether the subdural clot weighed about 25 gm.

Fig. 12 (Case 24).—Coronal sections (anterior surface) through the frontal and temporal lobes, showing the depth of the contrecoup bruising (Class 7).

the sixty-one fractures the brain injury was slight (or no injury was present), death resulting from other causes (in nine, from meningitis; in eight, from delirium tremens; in six, from broken bones; in five, from epilepsy; in two each, from bronchopneumonia and internal injuries; and in one each, from uremia, tetanus, drowning, syphilis and so-called pachymeningitis hemorrhagica interna).

Brain Injuries with Extensively Comminuted Fractures of the Cranium.—The greatest bruising of the

torn in thirty-nine (79.59 per cent.) of the forty-nine fractures; the temporal lobes in thirty-three (67.34 per cent.); the parietal lobes in sixteen (32.65 per cent.); the occipital lobes in nine (18.36 per cent.), and the cerebellum in six (12.24 per cent.). The contrecoup bruises were mostly of the undersurfaces of the frontal and temporal lobes, usually with many contusions of the type included in Class 4 (Figs. 31 and 32).

SUBDURAL TRAUMATIC HEMORRHAGES

Subdural traumatic hemorrhages result most frequently from lacerated cerebral veins where the brain is bruised. Also of importance are the bleeding, torn, cortical vessels. Infrequent sources of subdural hemorrhage are torn dural venous sinuses and the larger cerebral arteries of the base of the brain. In order to obtain facts for a better understanding of the location

Fig. 13 (Case 25).—Coronal sections (posterior surface) through the frontal and temporal lobes, showing contrecoup bruises of the left frontal lobe (Class 1), and intracerebral bleeding back into the left temporal lobe.

Fig. 14 (Case 25).—Coronal sections (posterior surface) through the occipital lobes. The bruise of the outside could not be seen from the undersurface with the cerebellum attached (Class 1), and both intracerebral bleeding beyond the margins of the bruise and rupture into a ventricle.

and extent of subdural hemorrhages, as much of the blood as could readily be removed from the torn brain without further injury was weighed, its distribution measured and the injury described, all with some accuracy.

Subdural Hemorrhages with Fractures of the Posterior Fossae.—Examinations were made in 136 of the 178 fractures of this group. In 115 of the 136 there was subdural hemorrhage, 104 contrecoup and eleven direct. In seventy-one of the 115 the blood weighed between 20 and 210 gm., but the most frequent weight of these large clots was about 40 gm. In the remaining forty-four there were usually only a few grams (from 1 to 10 gm.), and in a few from 10 to 20 gm. Of the large subdural hemorrhages, fifty-four were local, that is, confined to the front third or front half of the cranial cavity; seventeen were more widely spread over one side of the cerebrum.

Of these large hemorrhages, sixty-six were located altogether on one side. Two of the large subdural hemorrhages were contributed to by tears of large cerebral veins without severe injury to the brain.

Subdural Hemorrhages with Fractures of the Middle Fossae.—Examinations were made in 134 of the 166 fractures of this group. In ninety-eight there was subdural hemorrhage. Of these, in fifty-one the blood weighed between 20 and 310 gm., in the other forty-seven much less. In sixty-three the subdural hemorrhage was contrecoup, in thirty-five, direct. Of the large subdural hemorrhages, thirty-six of the fifty-one

were contrecoup, and fifteen, direct. Also, thirty-one of the large subdural hemorrhages were local, and twenty widely spread. The small subdural hemorrhages were only a few millimeters thick and extended from 1 to 10 mm. beyond the margins of the bruise from which the bleeding occurred. With increasing size, the subdural hemorrhages spread mostly up over the parietal lobe, the front margin advancing less than the upper and back margins.

Subdural Hemorrhages with Fractures of the Frontal Fossae.—In twenty-one of the forty-eight accurately described cranial injuries in this group there was subdural hemorrhage, and of these twenty-one, thirteen were direct and eight contrecoup. There were only six large subdural hemorrhages, five direct and one contrecoup, the latter beneath the tentorium cerebelli.

Subdural Hemorrhages with Extensively Comminuted Fractures.—In forty-three of the fifty fractures in this group, accurate records of the subdural hemorrhage or its entire absence were made. There were subdural hemorrhages in thirty-six, twenty large and sixteen small. Eighteen large subdural hemorrhages were contrecoup, and only two direct. Twelve small hemorrhages were contrecoup and four direct. In several cases there were both direct and contrecoup subdural hemorrhages.

Subdural Hemorrhages with Fractures of the Vault.—There were subdural hemorrhages in thirty-eight of the forty accurately described brains; twenty-eight of these were large and ten small. All but three of the large subdural hemorrhages were contrecoup, and fourteen of the large hemorrhages were local.

TRAUMATIC EXTRADURAL HEMORRHAGES

Bleeding, which splits the dura away from the cranial bones as a result of fracture, may result from laceration of the trunk or branches of one of the middle meningeal arteries, the dural venous sinuses,

Fig. 15 (Case 26).—Extensive, traumatic, comminuted fracture of the cranial bones, 55.9 cm. long. The cause of the fracture was undetermined. The scalp bruises were opposite the lambda. The patient was a white man, about 35 years of age.

Fig. 16 (Case 26).—Coronal section (posterior surface) of the frontal lobes. Contrecoup bruises of Class 3 of the left frontal lobe and Class 4 of the right frontal lobe are shown here.

the cerebral veins at the point of entrance into the superior longitudinal sinus, tears of the dura allowing free subdural blood to enter the extradural space, from the broken cranial bones, or from pericranial hemorrhages with comminuted depressed fractures.

There were extradural hemorrhages in 199 (39.48 per cent.) of the 504 fractures in this series. Of these 199, 104 (52.26 per cent.) were large enough to produce appreciable compression of the brain (from 20 to 246 gm.) and ninety-five were small, usually only a

few grams. Of the large extradural hemorrhages, seventy-three (70.19 per cent.) were with fractures of the middle fossae; fifteen (14.42 per cent.) with fractures of the posterior fossae; ten (9.61 per cent.) with fractures of the vault; three (2.88 per cent.) each with fractures of the frontal fossae and fractures listed as extensively comminuted. About 50 per cent. of the small extradural hemorrhages resulted from bleeding of the broken bones, and 20 per cent. from torn dural sinuses. The remainder were probably due partially to

Fig. 17 (Case 27).—Healing, traumatic fracture of the skull of undetermined cause, in a negro, aged 40. This illustrates the course of many fractures of the posterior fossae.

bleeding from broken bones and from pericranial hemorrhage.

Of the large extradural hemorrhages, forty-nine covered the temporal and parietal lobes on one side, thirty-four the temporal, parietal and occipital lobes on one side, fourteen one occipital lobe, six the frontal and parietal lobes on one side, and one the temporal and parietal lobes of both sides. Of these large hemorrhages, forty-nine were attributed to bleeding from the anterior branch of one of the middle meningeal arteries, forty-four from one of the posterior branches, three to laceration of the superior longitudinal sinus (the blood in two weighed between 25 and 30 gm., in the third about 60 gm. on each side, that on the left removed by the surgeon) and eight, in which there were fractures of the posterior fossae, from one of the transverse sinuses, the blood in none of the latter weighing more than 50 gm. Thirty-six of the large extradural hemorrhages were with fractures of the middle fossae passing through the anterior parts of the fossae in the squamous portions of the temporal bones, and thirty-seven with fractures that passed through the middle and posterior portions of the fossae. Comminution of the bones in the middle fossae occurred in less than half of the seventy-three large extradural hemorrhages; most of the fractures were of the linear type. Fifty-four of the large extradural hemorrhages were on the left side, forty-nine were on the right side, and one was on both sides.

The usual shape of the blood clot of the large compressing type is oval, the margins thinnest and the center thickest. The long dimension is obliquely directed up and back. The lower border is seldom lower than the middle temporal convolution, and the upper border is usually 1 or 2 cm. from the superior longitudinal sinus (only in six instances did the clot reach to the sinus). The thickest portion of the clot is usually at the middle of the outer surface of one of the parietal lobes so that the greatest compression of the brain is in a line drawn horizontally through the middle of the parietal eminences. The compression of

the brain is saucer-shaped (Fig. 30). The blood clots early, so that with death one or one and one-half days after the injury the clot adheres to the dura, when the calvarium is removed, rather than to the bones. Later the clot becomes so adherent that it is necessary to use the sharp edge of a knife to detach it. The average dimensions of a clot weighing about 100 gm. (this is an average weight) are 10 by 8 cm. and from 3 to 3.5 cm. thick.

In nine of the large extradural hemorrhages caused by fractures of the middle fossae, there was no bruising of the brain grossly visible; in thirty-three there were only superficial bruises like those included in Class 3 of brain injuries; in twenty-five there was sufficient bruising to allow from 5 to 20 gm. of blood to enter the

Fig. 18 (Case 27).—Typical traumatic hemorrhage (a) in the pons (Class 5), and (b) traumatic hemorrhage of the intracerebral type (Class 6), usually in the cerebral ganglions.

subdural space, and in six there were large subdural clots weighing from 40 to 120 gm. In none of the fifteen large extradural hemorrhages resulting from fractures of the posterior fossae was the brain without bruises, and in thirteen there were large bruises, contrecoup, and in the other two like those of Class 3. There were bruises of the brain in the remainder of the large extradural hemorrhages, frequently like those of Class 2. The proportion of contrecoup and direct bruises was approximately the same in fractures with large extradural hemorrhages as with the fractures without such hemorrhages.

There were decompression operations in twenty-three of the large extradural hemorrhages, in some with free blood still present at the time of the post-mortem examination in and beneath the decompression defect, and weighing from 60 to 120 gm. There were

Fig. 19 (Case 28).—Extensive comminuted, traumatic fracture of the cranial bones, 138.9 cm. long, in a white man, aged 52, who, while in the hospital suffering from chronic alcoholism, jumped from a second story balcony to the main floor and struck the cement floor head first. There were superficial contrecoup contusions of the brain (Classes 3 and 4) and moderate leptomeningeal hemorrhage. Death occurred in five minutes.

several decompression operations not included in these twenty-three in which the conditions postmortem precluded conclusions as to whether a large extradural clot was present before the operation; and for these no mention of a large extradural hemorrhage was made in the description of the operation by the surgeon. Sixteen of the twenty-three operations were with fractures of the middle fossae, three with fractures of the

posterior fossae, three with fractures of the vault, and one with an extensively comminuted fracture.⁴

TRAUMATIC LEPTOMENINGEAL HEMORRHAGE

Bleeding into the subarachnoid space or between the brain and pia (subpial) occurred in about 95 per cent. of all the fractures. Subarachnoid hemorrhage results most frequently from bleeding of bruises of the brain, but also from rupture of leptomeningeal vessels. Subpial hemorrhage results from tears of the pial arteries and cortical vessels. Subpial hemorrhage is seldom as extensive as subarachnoid hemorrhage, and is usually only enough to discolor the surface of the brain pink.

The extent and amount of subarachnoid hemorrhage is dependent on the size of the tear of the arachnoid membrane at the bruise (with large defects, bleeding occurs more readily into the subdural space⁵ than with smaller defects in which the margins of the bruise extend beyond the edges of the arachnoid tear), the bruise of the brain and the laceration of leptomeningeal vessels. Therefore, the amount of subarachnoid hemorrhage is not always proportional to the extent of the bruising of the brain. It is always thickest about the margins of the bruises and gradually thins

brain, and it was the only change sufficient to explain death in a few cases. As in other forms of edema of the brain, the convolutions are flattened, the cerebral veins relatively empty and flattened, the peripheral ends of the sulci closed up more or less tightly, the fluid in the leptomeninges greatly lessened; and when the edema is marked, the visceral layer of the arachnoid is almost dry when the dura is first removed, and by reflected light this surface of the arachnoid is finely granular because the little moisture present is heaped up by separating the two serous surfaces into almost microscopic droplets.

REPORT OF CASES

The failure on the part of police officers and physicians to recognize the presence of fractures of the cranial bones and severe brain injury, or to recognize these injuries only after several hours, requires some comment. Some of the cases reported concern the transfer of patients with fracture of the cranial bones from one hospital to another, in a few even after the nature of the injury was known.

Fig. 20 (Case 29).—Typical linear fracture of the midline of the posterior fossae, 21.2 cm. long. The patient, a white woman, aged 38, died about four days after falling down a flight of stairs.

Fig. 21 (Case 29).—The location and extent of the contrecoup tears (Class 1) of the frontal lobes (a) with rupture of the lateral ventricles, contusions (Class 4) of the temporal lobes (b) and traumatic subpial hemorrhage (c). A thin layer of clotted blood in the subdural space covered the entire brain, and at each tear there were about 5 gm. Altogether the subdural clot weighed 23 gm.

Fig. 22 (Case 29).—Coronal sections (posterior surface) through the frontal lobes, showing the depth of the tears and the petechial hemorrhages and edema of the surrounding brain tissue.

out centrifugally, sometimes covering an entire hemisphere. When extensive, from 1 to 3 mm. thick, the convolutions of the brain are hidden. When less extensive, the sulci stand out as a network because the blood tends to collect in them, and between them the convolutions form a pink meshwork. When slight, the convolutions are discolored pink ("traumatic lividity"). Although severe brain injuries and extensive leptomeningeal hemorrhage are frequently coincident, still there were a few extensively comminuted fractures associated with superficial bruises of the brain but with extensive leptomeningeal hemorrhage, and with some of these death occurred abruptly—from within a few minutes to several hours (Fig. 9).

The location of leptomeningeal hemorrhages corresponds in general to that of bruises in the various types of fractures.

TRAUMATIC EDEMA OF THE BRAIN

The most frequent change in brains of patients dying from fracture of the skull was traumatic edema of the

4. Although the period of time covered in the two articles is the same, a little discrepancy exists between the figures regarding extradural hemorrhages by us and the figures of Dr. Moody (*THE JOURNAL*, this issue, p. 511). This is due to the inclusion here of cases from the Hospital of the House of Correction.

5. Strictly speaking, the term "subdural space" is a misstatement because the inside of the dura is lined with the smooth, glistening parietal layer of the arachnoid, and for "subdural space," which is commonly used, there should be substituted "arachnoid space."

CASE 1.—A man, aged 45, who had fallen on a sidewalk, was taken to a police station and remained there from 11 p. m. until 12:15 p. m. the next day, when he was taken to the Cook County Hospital, where cerebral hemorrhage, left sided hemiplegia and basal skull fracture were diagnosed. He lived forty-five hours in the hospital.

Postmortem examination revealed a fracture of the right side of the vault, 17 cm. long, below this an extradural clot weighing 118 gm., covering the right motor region, and superficial direct contusions of the right cerebral hemisphere. The only external sign of injury was a bruise of the scalp about the right ear.

CASE 2.—An adult negro, after a street fight, while intoxicated, fell to the sidewalk and was taken to a police station, where he remained about twelve hours, lying on a cement floor. The following morning he was taken home, and then worked for three days as a porter in a saloon. On the fourth day he became "dopy" and was taken to the Cook County Hospital, where cerebral hemorrhage and lacerated scalp were diagnosed. He lived eleven days in the hospital, and five days passed between the time of injury and the entrance to the hospital.

Postmortem examination disclosed a fracture of the left half of the posterior fossa, 8 cm. long, contrecoup contusions of the frontal and temporal lobes, that of the right frontal 5 cm. deep, a huge subdural blood clot weighing 120 gm. of the front half of the right subdural space (brown and clotted firmly), and a healing laceration of the scalp near theinion.

CASE 3.—A man, aged 37, walked into a police station at 9 p. m., supposedly drunk. The next morning at 10:30 a. m.

he was taken to the Cook County Hospital, where he lived two and one-half days, cerebral hemorrhage and lobar pneumonia being diagnosed.

At the postmortem examination a fracture of the right half of the posterior fossa, 32.8 cm. long, extensive destruction of the tip of the right frontal lobe, 3 cm. deep, and a thin clot of blood in the subdural space covering the whole right hemisphere, but chiefly in front, were found. There was no sign of external injury of the scalp.

CASE 4.—A man, aged 50, fell down a flight of stairs about 1 a. m. and arrived at one police station at 2 a. m. the same day, where he remained for twenty min-

Fig. 23 (Case 30).—Traumatic, slightly depressed fracture of the skull, 19.5 cm. long. On the right side in the parieto-occipital region there was an extradural clot, 9 by 7 by 1 cm. in its largest dimensions, and weighing 40 gm. The patient, a white boy, aged 14 years, was struck by an automobile seven and one-half days before death.

Fig. 24 (Case 30).—A direct bruise at *a* (Class 2) under the depressed fracture, a contrecoup bruise at *b* (Class 3), and superficial contusions at *c* (Class 4). About the bruises there was leptomeningeal hemorrhage. There were several grams of blood subdural about the tear of the right temporal lobe, but none on the left side.

Fig. 25 (Case 30).—Coronal section (posterior surface) through the temporal lobes, showing the depth of the direct and contrecoup bruises.

utes and was then taken to another police station for medical care, remaining there until 8:40 a. m. the same morning, when he was taken to the Hospital of the House of Correction. Skull fracture was diagnosed and two decompression operations performed, one of each parietal region. He lived for three and one-half days in the hospital.

Postmortem examination revealed a linear fracture of the left posterior fossa, 9 cm. long, contrecoup bruises of the frontal and temporal lobes, that of the right frontal lobe being deepest, reaching to the lateral ventricle, a thin subdural clot covering the front half of the right cerebral hemisphere, and an extradural clot weighing 40 gm. in the operation defect of the left parietal region.

Fig. 26 (Case 31).—Linear fracture of the left middle fossa 9 cm. long. Three days and six hours before death this man, aged 42, fell while in a "fit," and struck his head on a cement sidewalk.

Fig. 27 (Case 31).—A contrecoup bruise at *a* (Class 3) and superficial contusions at *b* (Class 4), with subdural hemorrhage. There were 90 gm. of clotted blood in the subdural space on the right side covering the back half of the hemisphere. There was no bruising of the left cerebral hemisphere.

Fig. 28 (Case 31).—Coronal section (posterior surface) through the deepest part of the contrecoup bruise. The symmetry of the brain is due to compression by the subdural clot on the right side.

CASE 5.—A man, aged 22, after an unknown injury, and supposedly suffering from alcoholism, was taken to a hospital where he remained one day before skull fracture was suspected, after which he was taken to the Hospital of the House of Correction, where he lived two days. Skull fracture was diagnosed and a decompression operation of the left parietal region was performed.

Postmortem examination revealed a fracture of the left posterior fossa, 34.8 cm. long, contrecoup bruises of the right frontal and temporal lobes, and a direct bruise of the left half of the cerebellum, a large subdural clot on the right

side in the front half, an extradural clot filling the decompression bone defect and a bruise of the scalp behind.

CASE 6.—A man, aged 35, arrested and taken to a police station, remained twelve hours, suffering from alcoholism and epileptic fits, according to the police officers. He was taken to the Hospital of the House of Correction, where he lived fifteen hours. Skull fracture was diagnosed.

Postmortem examination revealed an extensively comminuted fracture of the back and base of the skull, with diastasis of both lambdoid sutures, altogether 60 cm. long; also there were deep contrecoup

coups bruises of the frontal poles, subdural clots covering both frontal poles, 30 gm. of blood in the decompression

defect of the left parietal region, and bruises of the scalp behind.

CASE 7.—A man, aged 40, was arrested and taken to a police station on account of alcoholism; after remaining there twelve hours he was taken to the Hospital of the House of Correction, where he lived twenty-eight hours, and where a decompression operation of the left parietal region was performed.

Postmortem examination revealed a fracture of the right parietal bone, slightly comminuted and 17 cm. long, a large contrecoup bruise of the right frontal lobe, blood subdural in front on the right side weighing 110 gm., and bruises of the scalp over the fracture.

In these cases there was failure to detect the presence of a skull fracture, or the fracture was discovered only after hours or days had elapsed:⁶

CASE 8.—A man, aged 28, was knocked to the ground by a falling sack of malt weighing 200 pounds. He was taken home, where he remained three days. Several physicians

6. Such unfortunate occurrences as these are less likely to be repeated, since they led to the institution of observation rooms at the Cook County Hospital, adjacent to the admittance department, where patients are kept over night or until the presence or nature of injuries is definitely ascertained.

examined him but none of them suspected the presence of a fracture of the skull, and one sent him to the hospital for the insane, where he lived seven hours and fifty minutes. No diagnosis was made in the hospital.

Postmortem examination revealed a linear fracture of the right posterior fossa, 8 cm. long, contrecoup bruises of the right frontal and temporal lobes and of the left occipital lobe, 40 gm. of blood on the right side behind (extradural) and a bruise of the scalp at the inion.

CASE 9.—A man, aged 42, while intoxicated, was tripped by a boy, October 9, and taken to the Cook County Hospital, where acute alcoholism and alcoholic dementia were diagnosed, and where he remained until October 22, when he was

where he remained four days and where laceration of the scalp was diagnosed. The physicians thought there was no skull fracture. He was discharged and went home, but, December 31, he suddenly became very sick and was taken to the Cook County Hospital, where he lived eighteen hours and where skull fracture was diagnosed.

Postmortem examination revealed a fracture of the midline of the posterior fossae, and through the right petrous bone; in addition there were also superficial contusions of the tips of the frontal lobes, meningitis of the base, and a healing laceration of the scalp at the inion.

CASE 13.—A man, aged 71, walked into a private hospital at 5:15 p. m. with lacerations of the back of the head, which were dressed there and which he did not know how he received. He walked out of the hospital. Two days later he was arrested and taken to the Hospital of the House of Correction, where he lived four days. Here he was irrational and unable to talk; alcoholism and delirium tremens were diagnosed.

Postmortem examination revealed a fracture of the left middle fossa, linear and 10 cm. long; also direct bruises of the left temporal and parietal lobes covered by adherent, brown subdural clots, weighing about 5 gm.

CASE 14.—A man, aged 48, fell from a moving wagon, January 20, and was taken home. On the 24th he went to a physician's office, and the physician thought he was suffering from alcoholism. He remained at home for three or four days more, wildly delirious and all this time in bed. He was then taken to the Hospital of the House of Correction, where acute alcoholism was diagnosed and where he lived two days.

Postmortem examination revealed a fracture of the midline of the posterior fossae, 39.2 cm. long, deep contrecoup bruises of the frontal and temporal lobes, large subdural clots about the bruises, an extradural clot in the left occipital region, and hemorrhages in the pons. There was extensive hemorrhage into the deep tissues of the scalp behind.

CASE 15.—A man, aged 45, was found on a sidewalk by the police at 1 a. m., was taken to the police station, where an ambulance surgeon diagnosed alcoholism, and where he remained until 2:40 p. m. the same day, when he was taken

Fig. 29 (Case 32).—Traumatic, comminuted and depressed fracture of the vault and base of the skull with independent fractures of the frontal fossae; also a decompression defect in which five loose pieces of bone were found by the surgeon. The superior longitudinal sinus was ruptured, and extradural bleeding resulted on both sides; that of the left was removed at the operation, and 60 gm. were found on the right side at the postmortem examination. The patient, a white man, aged 25, lived eleven hours and thirty minutes after being hit on the left side of the vault by a heavy iron bar during a fight.

Fig. 30 (Case 32).—Coronal section (posterior surface) through the brain 1 cm. posterior to the optic chiasm showing a tear (Class 2) at *a*, intracerebral bleeding from a bruise anterior to *b*, and the saucer-shape compression of the right cerebral hemisphere by the extradural clot weighing 60 gm. Traumatic hemorrhage of Class 7 at *c*.

sent to Oak Forest (an infirmary). October 24, he was readmitted to the Cook County Hospital and lived for two days. Skull fracture was diagnosed on the second entrance.

Postmortem examination revealed a comminuted fracture of the right posterior fossa through the right petrous bone, in addition to contrecoup bruises of both temporal lobes, that of the left, 9 by 3 cm., and reaching to the lateral ventricle, into which bleeding had occurred; also there was an extradural clot covering the right parietal lobe weighing 28 gm. There was no external sign of scalp injury. The extradural clots were brown and firmly clotted, the subdural mostly on the left side and weighing only a few grams.

CASE 10.—A man, aged 35, was struck by another man in a fight. It is not known whether the blow was struck with a fist or a weapon. He was examined by a physician immediately, who found "nothing wrong except complaint of headache." Suddenly, after two or three hours, he had a "fit" and was taken to the Hospital of the House of Correction, where he lived two days.

Postmortem examination revealed a depressed, comminuted fracture of the right temporal bone, 120 gm. of blood extradural on the right side in the parieto-temporal region, and a superficial bruise of the outside of the right parietal lobe. There were no external injuries, only a swelling in the right temple.

CASE 11.—A boy, aged 8 years, run over by an automobile, November 9, was treated at home until November 28, when he was taken to a private hospital and epidemic meningitis diagnosed. The same day he was removed to the Cook County Hospital by request of the health department, where he lived two days, and epidemic meningitis was again diagnosed. No one suspected skull fracture.

Postmortem examination revealed a small fracture of the ethmoid plate, superficial contusions (mostly subpial hemorrhage) of the frontal poles and left occipital lobe, and meningitis of the base of the brain (pneumococcus). Above the left eyebrow there was a scar.

CASE 12.—A man, aged 37, was in a fight, December 26, and fell to the sidewalk. He was taken to a private hospital,

Fig. 31 (Case 33).—Traumatic, extensively comminuted and diastatic fracture of the skull, 123 cm. long, with an independent fracture of the roof of the right orbit. The greatest scalp injury was over the back half of the right parietal bone. This man, aged 35, fell from a ladder head first, about two hours before death.

Fig. 32 (Case 33).—Multiple superficial, contrecoup contusions (Class 4) at *a*, a contrecoup tear of the undersurface of the left frontal lobe at *b* (Class 1), and a contrecoup bruise of the right frontal lobe (Class 2) at *c*. There were 190 gm. of blood in the left subdural space covering the entire left cerebral hemisphere, and only a few grams on the right side at *c*.

to the Hospital of the House of Correction. Here skull fracture was diagnosed, and he lived only thirty-five minutes.

Postmortem examination revealed a fracture of the right middle fossa 18.5 cm. long, 200 gm. of blood extradural in the right temporo-parietal region, superficial bruises of the outside of the right temporal lobe, and a thin clot of blood covering the right temporal lobe. There was no external sign of injury.

CASE 16.—A man, aged 49, found on the street by the police at 1 a. m., was taken to the police station, where he remained four hours, and then to a private hospital, where a physician diagnosed skull fracture and alcoholism. He was then transferred to the Hospital of the House of Correction at 6 a. m., and died the same day at 7:40 a. m. Skull fracture was diagnosed in the latter hospital.

Postmortem examination revealed a fracture of the right posterior fossa and traumatic diastasis of the right lamb-

of Correction, where he died, June 10, at 12 m. Basal skull fracture was diagnosed.

Postmortem examination revealed a fracture of the mid-line of the vault and posterior fossae, 50 cm. long; also there were extensive contusions of the undersurfaces of the frontal and temporal lobes of both sides, 16 gm. of blood subdural at the bruises, 30 gm. extradural along the superior longitudinal sinus, and meningitis of the left temporal lobe.

CASE 20.—A man, aged 70, was arrested for acute alcoholism and kept in a police station for ten hours; then he was removed to the Hospital of the House of Correction, where he remained two days; lobar pneumonia and delirium tremens were diagnosed.

Postmortem examination revealed a fracture of the right middle fossa, 17.5 cm. long, a large laceration of the right parietal and temporal lobes reaching to the lateral ventricle, 75 gm. of blood outside the dura and covering the right parietal region, and extensive hemorrhage into the right side of the scalp behind.

Other cases, such as these, concern cranial fracture recognized by physicians, and the patients transferred from one hospital to another:

CASE 21.—A man, aged 62, was run over by an automobile about one hour before entrance to a hospital, where he was given first aid; he was then taken to another hospital, where a decompression operation was performed above the right ear; here he remained for three or four days, and was then taken to the Cook County Hospital, where he lived three and one-half days and where old skull fracture, infected decompression wound and fractured ribs were diagnosed.

Postmortem examination revealed a fracture through the right petrous bone, 18 cm. long, superficial contrecoup bruises of the frontal and temporal lobes, fibrinopurulent

Fig. 33.—Time of death of ninety-five of the 104 patients dying with large extradural hemorrhages. Of the nine not shown in this graph, five were found dead and four died between the eighth and the twenty-second day after entrance to hospital. (Other details connected with some of these extradural hemorrhages, diagnosis, operations, etc., are given in the article by Dr. Moody.)

doid suture, altogether 24 cm. long, in addition to contrecoup bruises of both frontal and the left temporal lobes, all superficial except the latter, which reached to the lateral ventricle; there was blood in all of the ventricles of the brain. There was only a little subdural hemorrhage about the bruises. The scalp was lacerated at the inion.

CASE 17.—A man, aged 44, was arrested at 2 a. m. and taken to a police cell, where he remained until 11 a. m. the next day, the ambulance physician having diagnosed incipient delirium tremens. He became violent and was taken to the Hospital of the House of Correction, where he lived eighteen hours, and where delirium tremens was again diagnosed.

Postmortem examination revealed a linear fracture of the left lambdoid suture, right parietal bone and right middle fossa; there were also a contrecoup laceration of the left frontal lobe 4.5 cm. deep, a large subdural clot covering the top and side of the left frontal lobe, a small extradural clot in the right middle fossa, and hemorrhage into the right eyelid. There was no other sign of injury of the scalp, but in the deep scalp tissues of the right parietal region there was hemorrhage.

CASE 18.—A man, aged 24, to escape the police, jumped off a train into the Drainage Canal. At the Hospital of the House of Correction, where he stayed one week, no diagnosis was made. At home he complained of headache, and after ten days was removed to Cook County Hospital, where purulent meningitis was diagnosed, and where he lived one day. Postmortem examination revealed a fracture of the ethmoid plate and sella turcica, superficial contusions of both frontal lobes, and meningitis of the base.

CASE 19.—A man, aged 53, was found intoxicated by the police, 8:15 p. m., June 6; the police took him to a police station, where he fell on the floor; the wounds sustained were dressed at a private hospital, and he was again taken to the police station, where he remained until 11:30 p. m., June 7. He was then removed to the Hospital of the House

Fig. 34.—Time in twenty-four hour periods of death from fracture of the cranial bones and brain injuries of 403 of the 504 patients (upper line), and number of correct diagnoses during the same periods (lower line). The 101 remaining are not included because the time for eighteen of them was from eleven to twenty-two days, inclusive; twenty-seven had to do with persons found dead; for thirty-eight the records were incomplete; and eighteen concerned healed fractures. Any consideration of diagnosis must take into account the time under observation. Therefore, such charts as were used by Bissell and LeCount (A Consideration of the Relative Frequency of the Various Forms of Coma, THE JOURNAL, March 27, 1915, p. 1041; Feb. 17, 1917, p. 500) are continued here.

meningitis of the top of the brain, and purulent ependymitis.

CASE 22.—A man, aged 37, was struck by a street car at midnight, December 18, and taken to a private hospital, where skull fracture was diagnosed, and where he remained for five days. Because of inability to assure payment for hospital service, the patient was transferred to the Cook

County Hospital, where he lived until December 29, altogether eleven days.

Postmortem examination revealed a linear fracture of the midline of the base and left petrous bone, 38.5 cm. long; there were also lacerations of both frontal lobes, contusions of the temporal lobes and a direct bruise of the undersurface of the cerebellum, a few small subdural clots at the lacerations, and fibrinopurulent meningitis of the cerebellum.

TRAUMATIC FRACTURE OF THE CRANIAL BONES

CLINICAL CONSIDERATIONS, WITH ESPECIAL REFERENCE TO EXTRADURAL HEMORRHAGE *

W. B. MOODY, M.D.
CHICAGO

Between August, 1911, and June, 1918, 908 patients entered the Cook County Hospital for "skull fracture." This diagnosis was made certain for 547 of these either by operation or by postmortem examination. Fracture of the cranial bones was diagnosed by means of the roentgen ray for 105 others. The remainder (256) include patients whose illness and injuries were recovered from, and the conclusion that they also suffered from traumatic fracture of the cranial or other skull bones was not as adequately confirmed; for some small part of these, especially those in the hospital only a few hours, the diagnosis may

Chart 1.—Number of days under observation of sixty-three patients with extradural hemorrhage found at postmortem examination but not recognized clinically.

have been wrong. Postmortem examination was made in all deaths but sixty-two; in forty-one of these no fracture of the skull was actually demonstrated.

These considerations, as well as others shown in the accompanying table, are simply prefatory, since it is proposed to discuss here the extradural traumatic middle meningeal hemorrhages. Of the total 908 thought to be skull fractures (547 demonstrated as such), there were 100 with extradural hemorrhages of such size that compression of the brain by the blood was the chief cause of death. This condition was established for all the 100 patients either by operations, by postmortem examinations, or by both.

Diagnosis of traumatic extradural middle meningeal hemorrhage, found postmortem, was not made clinically in sixty-three instances. The time under observation of these sixty-three patients, whose compression of the brain was not recognized, is shown in Chart 1. It will be noted that twenty-four were in the hospital two days or more, the longest period for any single patient being twelve days.

Among other details regarding these extradural hemorrhages, shown in the table, is that all of the thirty-seven patients in whom the condition was recog-

nized had a decompression operation. Of this number, twenty-six died, twenty-one being operated on within twelve hours after entrance to the hospital (Chart 2). The longest period any one patient was under observation before operation was seven days. Following operation, eighteen died within twenty-four hours,

three inside of the next two days and one patient on the twenty-second day (lobar pneumonia).

As stated, sixty-three of the extradural hemorrhages were not recognized clinically.

Chart 2.—Time under observation before operation (solid line), and time between operation and death (broken line), of twenty-six patients with extradural hemorrhages, diagnosed and operated on. One patient dying on the twenty-second day with lobar pneumonia is not represented.

cally. The maximum weight of the extradural blood found postmortem was 246 gm., the minimum, 40 gm., with an average of 110.5 gm. for the sixty-three. In the clinical records for all but two there were symptoms generally regarded as useful in the recognition of compression of the brain; nine patients had hemiplegia, nine rigidity of the muscles on one side, and nine had convulsions; in twenty-three there was a positive Babinski reflex, and in some of the sixty-three the symptoms were combined in various ways.

In general, the pulse at the time of entrance and for a short time afterward was full and strong, from 65

* In sixty-two deaths, no postmortem examination was made. In twenty-one of these, fracture had been previously demonstrated. Roentgenologic diagnosis of skull fracture was made in 133 instances, 105 not being subsequently confirmed (by operation or postmortem examination). There was no roentgenographic evidence of fracture of the skull in ninety-six instances. Seventeen of these were found at necropsy to be fracture.

to 90, the temperature from 97 to 99 F. The most conspicuous features of pulse and temperature records, however, are that in the eleven recovering with decompression operation, the pulse and temperature were both lower than in other patients, and this pertains equally to conditions before and after operation.

* From the Cook County Hospital.

In twenty-seven of the clinical records blood pressure is recorded, without, however, anything of importance to comment on here because the observations were not repeatedly made for any single patient.

The other important features of these head injuries with one exception are indicated in the table. This exception concerns the records of blood examinations, and of all these 107 were found in the entire number (908). That there was an average leukocytosis of 15,300 apparently makes this condition of importance in the recognition of skull fracture. The number is so large that it is difficult to be accounted for by bronchopneumonia, and still less readily by meningitis; moreover, many of these blood examinations were made shortly after entrance.

POSTDIPHTHERITIC PARALYSIS

WITH REPORT OF TWO CASES *

SAMUEL W. BOORSTEIN, M.D.

NEW YORK

The most common form of polyneuritis encountered in children is diphtheritic paralysis. Not many of these patients, however, come under the observation of the orthopedic surgeon, because either the children recover without any treatment, or they are brought to him too late, just as the case used to be with patients with anterior poliomyelitis who were brought to him only after the deformities were marked. Thus, we do not have the frequent chance to see the proper benefit of early orthopedic treatment in diphtheritic paralysis. I am anxious to emphasize particularly the value of orthopedic treatment in relieving the distressing respiratory symptoms.

Diphtheritic paralysis occurs usually in the second or third week after the illness. The frequency of its occurrence after the injection of antitoxin is hard to state, while without antitoxin it occurs in about 5 to 15 per cent. of the cases.

A distinction may be made between a localized and a generalized paralysis. In localized paralysis the soft palate is usually involved. The palate alone may be involved or the muscles of the pharynx and larynx may also be paralyzed as well as the ocular muscles. Paralysis of the muscles of accommodation is present, but reaction to light remains. Paralysis of the pharyngeal muscles causes trouble in swallowing. There may be regurgitation of fluids through the nose caused sometimes by difficulty in swallowing and again by the entrance of food into the larynx, owing to anesthesia of the epiglottis and paralysis of the muscles of deglutition. The paralysis may involve the recurrent laryngeal muscles, causing hoarseness and aphonia.

In the generalized form, the extremities are next affected. In severe cases there may also be involvement of the muscles of the trunk and neck, and sometimes of the diaphragm. This distinguishes diphtheritic paralysis from other forms of multiple neuritis.

In cases in which the extremities are involved, there is at first weakness, followed by paresthesia and then pain. Then follow disturbances of movement, of sensation and of coordination. Walking is exceedingly difficult or impossible. Westphal's sign is always present, and Romberg's symptom frequently may be noted.

There are disorders of function of the bladder and the rectum. Paralysis of the cervical muscles may be so complete that the head cannot be held upright.

Respiratory paralysis may be due to involvement of the phrenic or the intercostal nerves. It is shown by occasional attacks of dyspnea and coughing. As the diaphragm is usually affected, the breathing is entirely thoracic. The respiratory movements are rapid, but irregular, shallow and ineffectual. There is cyanosis. The anxiety, distress and apprehension of the patient are sometimes terrible. There is constant dread of impending suffocation.

PROGNOSIS

Duration of the affection depends on its severity and extent. A patient may recover from a slight localized paralysis in a few weeks. The severer form lasts for many months, even for a whole year. Recovery is, as

a rule, to be expected, though often it is much delayed and frequently leaves deformities. The deglutition paralysis is quite serious. Respiratory paralysis, myocarditis and nephritis are annoying complications.

TREATMENT

Strengthening the diet is an important factor in the treatment of this condition; hence the patient should be fed by a stomach tube if he is not able to eat. The injection of serum is of doubtful benefit. Absolute rest in bed is important, and early contractures should be prevented. Massage and exercise are urgently recommended.

Fig. 1 (Case 2).—Position of collar. This photograph was taken after recovery.

REPORT OF CASES AND COMMENT

CASE 1.—History.—O. R., boy, aged 3 years, referred to me by Dr. Luttinger, Jan. 27, 1919, had had diphtheria four weeks before. No antitoxin had been administered, and paralysis of all four limbs developed two weeks after the attack.

Examination.—There was paralysis of all four limbs and of the neck. The patient appeared apathetic. There was a marked drooping of the head forward; the eyelids dropped; speech was distinctly nasal, and could not be understood at all. Respiration was thoracic, rapid, irregular and shallow. The patient could not sit up. There was marked interference with deglutition.

Treatment and Results.—After noting the interference with the pharyngeal muscles and fearing the stretching of the paralyzed neck muscles, I decided to apply something to prevent the stretching (devised on the same principle as apparatus used in anterior poliomyelitis or other forms of paralyzed muscles), and perhaps also to facilitate the respiratory difficulties. Remembering the principle of the Thomas

* Read before the Orthopedic Section of the Academy of Medicine, Oct. 17, 1919.

collar used to support the neck in cervical Pott's disease, I made a collar from thick felt, $1\frac{1}{2}$ inches in thickness and rather solid, and applied it in the vertical position. The width of the collar corresponded to the distance between the chin and the sternum when the head was slightly hyperextended (Fig. 1). This piece of felt was enveloped in softer felt, one-eighth or one-sixteenth inch in thickness. The collar was put on, encircling the neck, and the ends were sewed together. To my great surprise the child began to breathe better immediately. I then strapped the feet to prevent drop foot, and ordered the patient to bed, leaving the general treatment to the family physician, Dr. Luttinger. He took a culture from the child's nose and found diphtheria bacilli still present. He administered immediately 20,000 units of antitoxin. In a week a spinal brace was applied, the collar was left on, and massage was ordered. Later on, exercises were added. The exercises were, of course, the ones used in anterior poliomyelitis. In one and one-half months the child made a perfect recovery.

Though diphtheritic paralysis is curable, considering the severity of the symptoms, I believe that the orthopedic treatments, especially the application of the collar, hastened the recovery. I do not believe that the antitoxin was responsible for the recovery, as most pediatricians admit the uselessness of antitoxin in such a late stage. I was, however, skeptical about the orthopedic treatments till I had a chance to treat the second patient, who presented very interesting features:

CASE 2.—History.—S. W., boy, aged 7, admitted to the medical service of Dr. T. F. Reilly, Fordham Hospital, April 25, 1919, had had diphtheria two months previous to admission. He had received 5,000 units of antitoxin on the second day after the attack. Six weeks later paralysis of both upper and lower extremities developed. The child could not speak or swallow, and had to be fed by a stomach tube for ten days.

Examination.—When I was called to see the patient, April 29, there were paresis of both upper extremities and almost complete paralysis of both lower extremities with a tendency to drop foot. Breathing was thoracic, superficial and shallow. The face was dull and apathetic. The head drooped forward and the child could not hold it in an upright position. The eyelids dropped. The patient could not speak. He was still being fed by the stomach tube. If liquids were taken, regurgitation through the nose occurred.

Treatment and Results.—Remembering the benefit derived from the felt collar in the first case, I applied a similar one to the second child. Plaster casts were applied to the feet at the same time. The child began to improve immediately. The sudden improvement brought great joy to the kind nurses of the children's ward, who had shown a devoted interest in the case. Within a few days the child took food himself and showed marked improvement in his speech. May 8, massage and exercises were ordered; May 15, the child was able to take a few steps when he was supported. The casts were removed, May 31. The child continued to improve and, June 30, he was discharged, entirely cured, without any deformity whatever.

It was a source of joy to note the interest of the nurses of the children's ward, who spared no pains to carry out all orders. The last examination, Aug. 26, 1919, disclosed no paralysis or weakness of any muscle.

This case emphasizes a few points that are in contrast to those noted in the first case. Antitoxin was given on the second day, and still paralysis developed. The improvement after the application of the collar was remarkable: before its application the patient was getting worse all the time.

The child was cured without a second dose of antitoxin, which means that the improvements in the first case were also due entirely to the orthopedic treatments.

Though children with diphtheritic paralysis do recover, still the very rapid recovery noted in these two cases is undoubtedly due to the orthopedic methods employed.

The benefit of the collar can possibly be explained on the theory that mechanically it relieves the pressure on the trachea and esophagus induced by the pressure of the head. I am not, however, prepared to say whether that is really the reason.

529 Courtlandt Avenue.

Fig. 2 (Case 1).—Complete recovery. Note perfect symmetry of the face. Child is holding the brace which he was wearing before.

Effect of Alcohol.—The latest number of the special report series issued by the national health insurance medical research committee embodies the results of an investigation made on the effects of alcohol on manual work and the coordination of fine muscular movements. The pieces of test work to be done consisted in typing a memorized passage and correlating the number of errors; with the speed attained, in reproducing a given set of figures many times with a standard pattern adding machine and in pricking with an awl vertical rows of dots on a target suspended vertically at arm's length. The subjects included eight men and five women, and duplicate sets of experiments were conducted before and after the taking of moderate quantities of

alcohol in the form of wine, etc., both while fasting and with food. The results of the experiments went to show that alcohol produced some effect in all of the individuals tested by the typing and adding machine methods. The degree of effect depended largely on whether the alcohol was taken on an empty stomach or with food, for on an average it was about twice as toxic under the former conditions as under the latter. In some subjects a moderate dose of alcoholic liquid, taken with food, produced no measurable reaction. Such a nonreactive dose amounted to one glass of port (=18.5 c.c. alcohol) in a male subject, and to 4 ounces of port (= 22 c.c. alcohol) in a female subject. When the alcohol was taken with food, the effect was slightly longer in reaching its maximum. When alcohol (30 c.c.) was taken in 5 per cent. strength, the effect produced was about three fourths as great as when it was taken in 20 per cent. or 40 per cent. solution. A similar difference was observed when taking diluted brandy (10 per cent. alcohol) and "neat" brandy (37 per cent. alcohol).—*Medical Officer*, Nov. 15, 1919.

BLOOD PRESSURE IN OPERATIVE
SURGERY*

ALBERT H. MILLER, M.D.

PROVIDENCE, R. I.

As a factor in the preliminary examination, for judging the condition of the patient during operation and in following up the postoperative recovery, the blood pressure examination is of great importance although as yet imperfectly appreciated.

Fig. 1.—Simple blood pressure apparatus for use in operative surgery: stethoscope bell strapped to the arm and attached to ear pieces by tubing; sphygmomanometer cuff wrapped snugly around the arm and secured with a safety pin; gage and bulb connected to the cuff by tubing.

PREOPERATIVE EXAMINATIONS

The physical examination, which should invariably be made before any patient undergoes a surgical operation, is incomplete without a study of the blood pressure. Some of the pathologic conditions which bear directly on the chance of recovery from the operation and the anesthetic are indicated by characteristic blood pressure readings. Nephritis is accompanied by a marked increase in the systolic and diastolic pressures. Tuberculosis is regularly accompanied by a low systolic pressure. Myocarditis is indicated by a low pulse pressure. Incompetence of the aortic valve is indicated by a high pulse pressure and a low diastolic pressure. In some cases of aortic disease and also of exophthalmic goiter, the fourth phase of the blood pressure wave extends to zero and the fifth phase is lacking. With the stethoscope applied at the elbow or at the popliteal space, the pulse sounds are heard without constricting the limb. In other cases showing the high pulse pressure of aortic incompetence or of exophthalmic goiter, the same condition is found while the patient is under ether anesthesia, but this passes away early in the recovery.

For determining the index of the patient's resistance, the rule given by Moots¹ is of great value. It may be thus stated:

The pressure ratio, a fraction having the pulse pressure as numerator and the diastolic pressure as denominator, may be normal between 40 and 60 per cent. If the ratio is either high or low, there is reason to apprehend danger. If the ratio lies between 25 and 75 per cent., the case is probably operable; if outside these limits, it is probably inoperable.

In checking up the accuracy of this rule in a series of 1,000 cases, it was found that in the operable cases, 3.23 per cent. of the patients died and 96.77 per cent. recovered; in the inoperable cases, 23.07 per cent. of the patients died and 76.93 per cent. recovered.²

ROUTINE EXAMINATIONS DURING OPERATIONS

The importance of routine blood pressure tests in the course of surgical operations is not generally appreciated. Catastrophes occur daily which might have been foreseen and prevented by attention to this subject. The apparatus required is simple. The bulb or pump with release valve, for raising or lowering the pressure in the cuff, is joined to the gage by a short piece of tubing. By a T, inserted in this tubing, connection is made with the usual cuff by a tube 3 feet in length. The gage is attached to the patient's pillow so as to be in the anesthetist's field of view. The cuff is wrapped smoothly about the arm and the outer folds secured by a safety pin. A flat stethoscope bell is connected to ear-pieces by a tube 3 feet long. The bell is provided with an elastic garter for keeping it in place at the bend of the elbow. This apparatus is put in place before the anesthesia is commenced. At five or ten minute intervals the anesthetist takes, by the auscultatory method, the systolic, diastolic and pulse pressures and records them on a chart on which are also entered the pulse and respiration rate, and other data of interest concerning the anesthesia or the operation. Changes in the blood pressure will result from excitement, from obstruction to respiration, from overdose of the anesthetic, from changes in the position of the patient, from unusual temperature in the operating room, and from hemorrhage or as the result of operative manipulation.

Hot and cold applications within the abdomen cause a marked fall in the systolic pressure, but the change

Fig. 2.—Blood pressure apparatus from anesthetist's point of view: gage attached to pillow in easy view, thus obviating danger of leaving pressure in the cuff between observations; during operations, the arm to which the apparatus is attached need not be exposed.

is usually transient. A drop in the temperature of the operating room is followed by a corresponding fall in the blood pressure, especially in the cases in which there is considerable visceral exposure. When the operating room temperature is raised the blood pressure slowly recovers. An operation performed in a room at a temperature of from 50 to 60 F. is certain to be accompanied by a considerable fall in the blood pres-

sure, which will be especially marked if the incision is extensive and if there is a large exposure of viscera. The operating room temperature should be a matter of concern and should not be allowed to fall below 70 F. in the course of any major operation.

EFFECT OF POSTURE

To determine the effect of posture on the blood pressure during operations under anesthesia, a series of 1,000 cases has been tabulated with regard to posture and blood pressure. In this study, some confusion in the determination of standard pressures for comparison was inevitable. The standard pressures were taken in the dorsal position; some on the day before operation, some on the day of operation before the commencement of anesthesia, and some in the course of the anesthesia and the operation. The standard pressures taken on the day before operation are sometimes increased because of excitement. On the day of operation, the readings are frequently depressed as a result of the technic of preparation, including catharsis and deprivation of food and water, and following preliminary medication. The pressures taken in the course of operations may have been modified by the action of the anesthetic or by operative manipulations. The pressures for comparison in the dorsal position have been taken from ten to twenty minutes after the commencement of anesthesia. Pressures in other positions have been taken at

4.1 per cent., and diminished in 57.2 per cent. of the cases.

These figures indicate that in this series of operations under anesthesia: In the dorsal position, the systolic pressure tended neither to increase nor diminish; in the lithotomy position, it tended to increase; in the combined lithotomy and Trendelenburg position, the increase in the systolic pressure was exaggerated; in the Trendelenburg position, the pressure tended to decline; and in the reverse Trendelenburg position, there was a marked tendency to decline in the systolic pressure.

The routine use of the reverse Trendelenburg or Fowler position following certain types of operation has undoubtedly contributed to unnecessary fatalities. Its use must be condemned unless the patient's condition has first been proved satisfactory by blood pressure tests.

EFFECT OF ANESTHESIA

By a light degree of anesthesia, in the absence of efficient dosimetric methods, we refer to a condition of anesthesia characterized by quiet respiration, a contracted pupil, with no increase in the secretion of perspiration, mucus and tears, and the pulse and blood pressure not markedly affected. The anesthetics, when carefully administered, do not usually cause a rise in blood pressure. With cyanosis, the systolic pressure is raised. If excitement be present, the systolic and diastolic pressures and the pulse rate are increased. A profound degree of general anesthesia is likely to be accompanied by a rapid decline in blood pressure. The spinal administration of anesthetics is followed by

a distinct drop in blood pressure which frequently reaches the danger zone; in one instance, the systolic pressure had declined to 20 mm. ten minutes after the administration.

The effect on blood pressure of overdosage with anesthetics is not generally realized. Cholecystectomy, hysterectomy and other major operations if free from hemorrhage may be performed under light anesthesia without marked effect on the blood pressure or the pulse rate. Under the overdosage of the anesthetic frequently employed, a tremendous decline in blood pressure is regularly noted.

INDEX OF SURGICAL SHOCK

A falling blood pressure with an increasing pulse rate is the most certain indication of the incidence of surgical shock. For determining the presence of shock, McKesson's³ rule is an important guide. It is thus stated:

With a pulse rate of 120 or more, a pulse pressure of 20 mm. or less, and a diastolic pressure of 80 mm. or less in a patient, who, at the beginning of the operation, had presented normal pressures, frank shock has occurred. If these low pressures are continued without improvement for more than half an hour, a vicious circle is generally established, which, without treatment, will cause the death of the patient.

In checking up the accuracy of this rule, it was found that in patients who were within the danger zone as determined by the rule for more than twenty-five minutes, the mortality rate was 69.23 per cent.²

CONCLUSIONS

Before every surgical operation, a physical examination should be made including an estimation of the blood pressure.

During operations, blood pressure tests provide an invaluable index to surgical shock, hemorrhage, and anesthetic overdosage.

The sphygmomanometer should be used not only in selected cases but also as a routine measure. In this way we shall become accustomed to normal variations in the blood pressure during operations and be able to detect the signs which indicate vital changes in the patient's condition.

The Fowler position should not be used after an operation until the circulatory condition has been proved to be satisfactory by blood pressure examinations.

The Doctor's Dilemma.—The doctor, like his brother professional men, finds himself in a tight place in these days where income and outgo make such close connections. But the doctor has an additional grievance. The salaried man gets his pay, such as it is, on time. The doctor frequently has to wait for his and sometimes waits in vain. All the other bills apparently take precedence over the doctor's. Not, surely, because his services are less valued or because he is less in need, but more because he has the feeling that in his profession service should rank above profit. Were he to emulate the tradesman, he would run the risk of lowering the splendid tradition of his brotherhood. A minister almost never sues for his salary. A doctor must look at it in somewhat the same way. If the ethics of a profession stand in such wise, an obligation of honor surely lies on those whom the profession serves to accept the same high standard and live up to it.—Milwaukee Journal.

AN OUTBREAK OF BOTULISM*

DWIGHT L. SISCO, A.M., M.D.

BOSTON

The outbreak of botulism reported here occurred in January, 1920, in an Italian family, living in the Bronx, New York City. The source of the toxin was shown to be a glass jar of factory packed California ripe olives. These olives, consumed as such and also as part of a salad, caused the death of six of the seven members of the family who ate of them. Bacteriologic examination of these olives was carried out by Mr. Paul Orr in the Department of Preventive Medicine and Hygiene of the Medical School of Harvard University; Dr. Charles Krumwiede of the Research Laboratories of the New York City Department of Health; the Microbiological Laboratory at Washington, D. C., and Dr. Gettler of Bellevue Hospital, New York. At the present writing it is known that at least two of these laboratories have been successful in demonstrating the presence of *Bacillus botulinus* and its toxin. Mr. Paul Orr, working in this laboratory, has succeeded in isolating from the remainder of the olives used by the family a bacillus morphologically and culturally characteristic of *B. botulinus*. A Mandler filtrate of the liquor in which the olives not eaten were found proved toxic to animals as follows: When injected intraperitoneally into a 12 gm. white mouse, 0.004 c.c. of this filtrate caused death in seventy-four hours. One-tenth c.c. of this filtrate given to a 200 gm. guinea-pig by mouth resulted in death in sixty-eight hours. A 410 gm. guinea-pig which was given 3 c.c. of the same filtrate, by mouth, was found dead twelve hours later. One-tenth c.c. of antitoxin (Graham) injected intraperitoneally and simultaneously with 0.1 c.c. of the Mandler filtrate failed to protect an 11 gm. white mouse, death occurring in four hours. This indicated that the toxin in the olives was formed by an organism not homologous to the one used by Graham in the preparation of the antitoxin. The toxin was destroyed by heating to 80 C. for two minutes.

There were eight members in the D. family: Mary, the mother, aged 33; Paul, the father, aged 36; Dominica, a son, aged 16; Antonio, a son, aged 13; Angelo, a brother of Paul, aged 26; Dominick, a brother of Paul, aged 46; Lena, a daughter, aged 9, and Joseph, a son, aged 7. Dominick lived down town in Manhattan, but all the other members of the family lived together in the Bronx. Dominick frequently brought ripe olives to his brother's home, and it was he who furnished the jar of olives and made the salad that caused the deaths.

The diagnosis was not made until a necropsy performed on the body of the second member of the family to die suggested the possibility of food poisoning. It was then recalled that an outbreak of botulism, due to ripe olives (the Detroit outbreak), had been described in a very recent journal. Investigation of this clue led to the discovery that all the members of the family had partaken of ripe olives, and were presenting symptoms of botulism. A detective was immediately sent to the D. home with orders to confiscate all foodstuffs in the house.

* This work is a part of the investigation of food poisoning, conducted under the direction of Dr. M. J. Rosenau, professor of preventive medicine and hygiene, Medical School of Harvard University. The investigations are made under the auspices of the Advisory Committee on the Toxicity of Preserved Foods of the National Research Council, and under a grant of the National Canners Association.

The investigation here reported was begun after four of the family were dead, one so far gone that he could give no information, and one so ill that he could hardly talk. The two surviving ones were children, aged 9 and 7, respectively, and consequently could not be depended on for much information. As a result, many very desirable details are lacking in this report. Through the kindness of Mr. B. R. Hart, Chief, Eastern District, United States Food and Drug Inspection, I was able to work with the government inspectors, and thus secure much information which would not otherwise be available. Inspectors Olof Olsen and F. L. Wollard, U. S. Bureau of Chemistry, the Fordham Hospital, the New York City Health Department, the Medical Examiner's Office, and Dr. Louis J. Ferrara offered all the assistance possible.

EPIDEMIOLOGY

The olives responsible for this outbreak were "giant" size, California ripe olives, packed in 14 ounce (net weight) glass, hermetically sealed jars. They were not the same brand of olives that were responsible for the outbreaks in Canton, Ohio, and in Detroit in August and October, 1919, respectively. The present available information makes it seem quite probable that they came from an entirely different section of California than the olives responsible for the first two outbreaks. The olives concerned in the present outbreak were packed by a California olive company for a New York City distributing company. They bore the private label of the latter company. The distributing company ordered the olives, Oct. 11, 1917, and received them, April 4, 1918; but they rejected this shipment because the olives were not of good quality, branding them as "impossible" and declining to put them on the market under their label. The olives were then placed in a New York warehouse by the California company. They were resold and placed on the market by the California olive company, which in the meantime had undergone a reorganization. After considerable shifting and circulation among several New York distributors and wholesale dealers, thirty cases, 720 bottles, of these olives, were sold, Oct. 28, 1918, to the retail dealer who, in turn, sold the infected jar to Dominick. The New York distributing company protested, not only to the California company, but also to dealers in New York, the sale of these olives which they had rejected, under their private label; but the labels were not removed, and the olives continued on the market. During the shifting and circulation of these olives, several of the persons who handled them stated that many of the jars were spoiled and unfit for sale. One man, on purchasing a retail grocery store, threw away thirty-seven jars because they were not in good condition. Whether or not any of these numerous spoiled jars contained *B. botulinus* will probably never be known. Of the thirty cases sold to the grocer who sold the olives to Dominick, only five and one-half cases, 131 of the original 720 bottles, were on hand when confiscated by the health authorities. The remaining 589 bottles had been sold to customers in the neighborhood, none of whom, however, had made any complaint to the storekeeper. Whether or not any illness had occurred in these homes, attributed to other causes, since the sale of these olives began (Oct. 28, 1918) was not ascertained.

The exact date on which Dominick purchased the olives that caused the outbreak is not definitely known;

but he says it was sometime after Jan. 1, 1920. Thus it will be noticed that the jar of olives responsible for the outbreak had been packed for at least twenty-six months, for it had been in New York City since October, 1917.

Among the things commandeered by the detective at the D. home was one-half bottle of ripe olives and two empty olive jars of the same size and bearing similar labels. The tin cover of the half filled jar was missing, but two other tin covers were found each bearing the same batch number. In view of all the facts concerning these olives, there is practically no doubt that they all came from the same batch. Dominick, before his death, stated that he had purchased these three jars of olives at the same store, one just before Christmas, one just after Christmas, and the third shortly after New Year's, 1920. They were carried to the D. home by Dominick as a delicacy, one jar at a time. Definite facts are not available, but it is reasonable to assume that one jar was consumed before another was opened, thus making it seem quite probable that the third jar was the one that contained the toxin.

As pointed out in the case histories, there is no definite proof that Mary, the first to die, ate ripe olives; but certainly all information available indicates that she opened this third jar of olives, January 8 or 9, and ate some of the olives, replacing the jar on its accustomed shelf, where it was later found by the other members of the family. The unsettled conditions and irregular status in the home following her death and funeral make it seem very probable that no olives were eaten until the following Tuesday night, January 13, when the rest of the family gathered at the home in the evening for supper. As accurately as could be attained, this meal consisted of macaroni with tomato sauce and a salad prepared from ripe olives, anchovies, pickled peppers, olive oil and vinegar. Dominick stated before his death that he prepared this salad, saying that the olives came from a jar taken from a shelf over the kitchen table, that this jar had been previously opened, and that "several" olives had been removed. He said that the other members of the family were seated about the table as he prepared this salad. Some of the olives were removed from the jar and placed on a plate, from which he took them one at a time, to cut them up for the salad. According to him the other members of the family helped themselves to these olives while awaiting the completion of the salad. He did not know whether some ate more heartily than others. He did state, however, that he noticed nothing wrong about the odor or taste of the olives, but on the contrary found them "very good," saying that he "liked them."

No statements concerning the odor and taste of the olives were obtained from other members of the family before they died. When asked if he washed the olives before putting them in the salad he nodded an affirmative answer, but this assertion is open to much doubt in view of the other facts of the case. Paul, the father, stated before his death that "everybody" ate olives. Lena, 9 years old, developed no symptoms, but insists that she ate one whole olive which her father handed her at her request. When asked why she ate no more she simply stated that she "didn't want any more," but said that she found neither the taste nor the odor disagreeable; that, in fact, she "liked them." She did not eat any of the salad. She said

that her brothers, Dominica and Antonio, were very fond of ripe olives, and that she saw them taking olives from the plate and open jar while the salad was being prepared. She also said that her mother was very fond of olives, and that she had seen her, on several occasions, remove olives from an open jar and eat them.

The exact hour at which this meal occurred is not known, but it is reasonable to assume that it was not before 6 p. m. Assuming such to be the case, definite symptoms of botulism had developed in all those who showed symptoms at all in from four to fifty hours after this meal.

REPORT OF CASES

CASE 1.—Mary, the mother of the family, was the first to become ill. Information concerning her death is found in the following statement made by Dr. L. J. Ferrara, her physician:

"Jan. 10, 1920, I was called in at 8 a. m. and saw the mother, Mary, in bed suffering from a choking sensation, with partial blindness. The history obtained was that she had been worrying and crying the entire night before. Vomiting began at 10 p. m., January 9. I looked in her throat and found it practically normal. I asked her to take a drink, which she was unable to swallow. I then examined the eyes and found them to react to light; she could recognize me and various objects which I held up to her; she said her vision was blurred. Temperature was normal. Her pulse was about 80, snappy and bounding. Reflexes were normal. There was no tenderness or pain in the abdomen. History as to possible poisoning from alcohol or food products was negative. At 12 noon (of the same day) I was recalled and found on my arrival that the patient was dead.

"On questioning, the husband, Paul, stated that his wife had been treated two years ago for kidney trouble; that since then she had had, off and on, puffiness of the eyes and some swelling of the limbs. In view of this history I signed her death certificate as 'uremia, chronic nephritis,' ascribing the dimness of vision to albuminuric retinitis."

No definite data concerning the consumption of ripe olives by her is available, but all the information at hand makes it seem quite probable that on January 8 or 9 she opened the contaminated jar of olives and ate two or three or more of them. The fact that ripe olives had been kept in the house, that they always stood on a shelf over the kitchen table, and that Mary was particularly fond of them and had been observed to eat olives taken from such a jar on previous occasions, makes such an assumption quite reasonable. This assumption is further substantiated by the fact that the jar of olives used later by the family in the salad was found open with "several" olives removed. No definite statement as to the number actually missing could be obtained. There is no way of telling how soon after eating olives her symptoms appeared or how long symptoms had been present before she was seen by her physician, although it is stated that she vomited ten hours prior to the visit of her physician. It seems reasonable to estimate that death occurred fifteen or twenty hours after the onset of symptoms.

CASE 2.—Dominica, a son, aged 16, became ill Tuesday, January 13, about 10 p. m. Dr. Ferrara's statement concerning him is as follows:

"I was next called, January 14, at 7 a. m., to see the son, Dominica. The history, obtained from the father and verified by the patient, was that he was seized on the evening of January 13, about 10 p. m., with a choking sensation and inability to swallow, with a partial loss of vision, vomiting and extreme weakness. He was unable to talk, owing to the pharyngeal paralysis, and wrote answers to my questions on a piece of paper. His mental condition at the time was normal. He did not complain of abdominal pains. Dominica was in bed and was unable to open his eyes completely,

having a ptosis of both upper lids. His pulse was very weak, about 80. Temperature was normal. There was no tenderness of the abdomen. There was no diarrhea, the bowels not having moved at all. He could recognize various objects, such as matches, pencil and paper, but his vision was also dim. I washed his stomach with plain water, and removed a brownish, dark fluid, with a putrid smell, 4 quarts of water being required before the liquid returned clear. I put in through the tube a cup of strong black coffee to stimulate him, and ordered whisky. I sent an ambulance and had him removed to Fordham Hospital, where he arrived about 10 a. m., and died within a few minutes (thirty-two) after his arrival."

The diagnosis on admission to the hospital was "paralysis of the throat," "migraine" and "hysteria." He failed to react to one-thirtieth grain of strychnin sulphate, subcutaneously. He was mentally clear and conscious to the last, and there were no convulsions.

The onset of symptoms occurred four hours after eating the olives, and death occurred twenty-four and one-half hours after the onset of symptoms, or twenty-eight and one-half hours after ingestion of the olives. Information obtained from other members of the family shows that Dominica was unusually fond of ripe olives and always ate freely of them whenever they were available. This fact, together with the rapid onset of symptoms and the profuse vomiting (suggestive of gastric irritation due to a large amount of toxin) makes it seem quite probable that he partook more freely of the olives than the others. It was the necropsy on his body which led to the suggestion of food poisoning and later to the diagnosis of botulism.

CASE 3.—Paul, the father, aged 36, was the next member of the family to fall ill. Wednesday afternoon, January 14, he noticed that he had considerable difficulty in expectorating. When seen by his physician at 4 p. m., there was dimness of vision, diplopia, marked prostration and weakness, difficulty in swallowing and talking, and thick, glairy mucus in the mouth and throat which could be evacuated only with great difficulty. He immediately walked to the Fordham Hospital, the admission diagnosis being "paralysis of throat and partial blindness." His pupils reacted only sluggishly to light and accommodation. Other reflexes were not influenced. He vomited a small amount of material which was said to have a putrid odor. There was no diarrhea, but instead marked constipation. There soon developed ptosis of both eyelids and complete aphonia. He also complained of a distressing sense of pressure or weight in the epigastrium. Perspiration became very profuse. Edema of the soft palate and pharynx developed. As respiration became more difficult, cyanosis became more marked, and death, due to respiratory paralysis, resulted. Mental clearness was present throughout.

The highest recorded temperature was 99.8 F. The pulse rate never exceeded 92 beats a minute, and the greatest respiratory rate recorded was 24 a minute. The white blood count was found to be 10,600. The differential blood count was not abnormal and presented nothing of interest. Lumbar puncture revealed a sterile and otherwise negative fluid under pressure sufficient to cause one-half inch projection of the stream. The urine presented nothing of interest. The onset of symptoms occurred twenty-two hours after eating the olives, and death occurred forty hours after the onset of symptoms, or sixty-two hours after ingestion of the olives.

CASE 4.—Antonio, a son, aged 13 years, became ill at 8 p. m., Wednesday, January 14. He became much alarmed when a sensation of choking developed in his throat, and at 4:45 a. m., January 15, walked into the Fordham Hospital. His pupils were dilated and reacted sluggishly to light and accommodation. Other reflexes were not obtained. There was ptosis of both eyelids, dimness of vision, great weakness and prostration, difficulty in swallowing and speaking, with later development of complete aphonia, constipation, thick, glairy mucus in the throat, profuse perspiration

and marked respiratory difficulty and cyanosis, which progressively increased as death due to respiratory paralysis approached. At no time was mental clearness clouded.

The highest figures recorded for temperature, pulse and respiration were 100.2 F., 120 and 28, respectively. The pulse was irregular, but of good volume. The Wassermann test was negative. The urine showed a very few pus cells, but was otherwise uninteresting.

The symptoms appeared twenty-six hours after he had eaten the olives. Death occurred forty-three and one-half hours after the onset of symptoms, or sixty-nine and one-half hours after ingestion of the olives. It is not possible to say how many olives this patient consumed, though the available information makes it seem quite probable that he ate freely of them.

CASE 5.—Angelo, a brother of Paul, aged 26, also became ill at 8 p. m., Wednesday, January 14. His first symptoms were dryness of the throat, thick speech, difficult expectoration and a choking sensation. He was admitted to the Ford-

CASE 6.—Dominick, aged 46, brother of Paul, walked into the Fordham Hospital at 4:30 a. m., Friday, January 16, complaining of a choking sensation and dimness of vision. On Thursday, January 15, he had felt considerable apprehension, and somewhat indefinite indisposition, but noticed nothing definite until about 8 p. m., when there was difficult expectoration and some dimness of vision. He followed rapidly the course of the others, presenting dilated pupils which reacted sluggishly to light and accommodation, but no involvement of other reflexes, diplopia, ptosis of both eyelids, great muscular weakness and prostration, difficulty in speaking and swallowing, constipation, mucus in the throat, profuse perspiration, a sense of chilliness, and gradual failure of respiration with accompanying cyanosis, leading to the terminal respiratory paralysis. He became somewhat irrational about an hour before death.

The highest recorded values for temperature, pulse and respiration were 99.6, 120 and 24, respectively. The urine contained a very few pus cells, but was otherwise negative.

ham Hospital at 3:30 p. m., January 15, the admission diagnosis being "paralysis of throat muscles." His pupils were dilated, reacting only sluggishly to light and accommodation. Other reflexes were present and active. There was ptosis of both eyelids, dimness of vision, great muscular weakness and prostration, difficult speech leading to complete aphonia, dysphagia, and some pain in the throat. Constipation was marked. The thick glairy, tenacious mucus was present in the throat. There was a distressing sense of pressure or weight "at the pit of the stomach." Profuse perspiration also was present. The difficulty in respiration grew progressively worse, and cyanosis developed culminating in respiratory paralysis with death, the patient maintaining mental clearness until shortly before death.

Temperature, pulse and respiration were not recorded in excess of 99.6 F., 120 and 24, respectively. The urine, other than a very few pus cells, presented nothing of interest.

The onset of symptoms occurred twenty-six hours after the olives had been eaten. Death occurred seventy-two hours after the onset of symptoms, or ninety-eight hours after ingestion of the olives.

The first symptoms appeared fifty hours after he had eaten the olives. Death occurred seventy-four hours after the onset of symptoms, or 124 hours after ingestion of the olives.

This patient stated before his death that he felt quite sure he had eaten only about two olives which had been chopped up and put in the salad.

CASE 7.—Lena, aged 9, a daughter, was taken to the Fordham Hospital, January 14, with her father. She was presenting no symptoms at this time, but was admitted for observation merely as a precautionary measure. She was quite positive that she had eaten one ripe olive, January 13, during the preparation of the salad, but had eaten none of the salad. During the night of January 17, it was felt by some of the physicians that she showed some hesitancy in speech and slight ptosis of the right eyelid in addition to constipation. There was, however, no consensus as to the presence of these symptoms, so that it seems impossible to state with finality that she exhibited definite symptoms. She was later discharged from the hospital apparently none the worse for her experience.

Joseph, aged 7, a son, was taken to the home of friends after his mother's funeral, and was not present, January 13, when the other members of the family became infected. He ate no olives and developed no symptoms.

SYMPTOMS AND PHYSICAL SIGNS

The symptoms and physical signs were much the same in all six cases. As stated above, the onset of symptoms varied from four to fifty hours after ingestion of the contaminated food. In general, the onset was gradual and not of such a nature as to cause apprehension on the part of the patient. Reference to the accompanying chart and the individual case histories will reveal the details of each case.

The incidence and progression of symptoms was not identical in all the cases, but followed the same course in general. The first intimation of trouble seemed to be rather an indefinite indisposition, followed rapidly by muscular weakness which gradually increased to great prostration. Difficulty in expectorating, thick speech, dryness of the mouth and dysphagia were among the first symptoms noted, seemingly due to mucus in the throat and perhaps also to beginning paralysis of the pharyngeal muscles. As the disease progressed the mucus became thicker, glairy and more tenacious, and could not be evacuated either up or down. It was the source of much discomfort, and the patients made vain efforts to remove it with their fingers or handkerchiefs. As the paralysis of the muscles of the throat increased, swallowing became more difficult and the ability to speak diminished toward an ultimate complete aphonia. A sensation of choking, with more or less sense of constriction about the throat, was noticed early in the disease by four of the patients.

The various eye symptoms were among the earliest manifestations. Dimness of vision, a blurring and mistiness, was noted by all the patients. Diplopia was remarked by only two of the six, but it is quite probable that it was present in the others. Dilated, sluggishly reacting pupils were observed in three cases. Other reflexes were present and active in three of the four cases examined. Ptosis of the eyelids invariably developed. Nystagmus was observed in one case.

Vomiting occurred in three of the cases and, as far as the evidence was available, was associated with large doses of toxin, which apparently produced gastric irritation prior to paralysis. In this outbreak, as in the Detroit cases reported by Jennings, Haass and Jennings,¹ the patients who vomited at the onset died sooner than the others. Diarrhea was not present in any case but, on the contrary, constipation was evident in all, evidence which may be interpreted as local, peristaltic paralysis. A feeling of pressure and "weight at the pit of the stomach" was remarked by two of the patients. A feeling of chilliness and profuse perspiration was present in four cases. Mental clearness, maintained until shortly before death, was strikingly characteristic. All the patients were drowsy and somewhat comatose immediately before death. One patient became somewhat irrational about an hour before death. Dyspnea did not manifest itself so much in rapidity as in difficulty of breathing. The highest respiratory rate recorded for any of the six patients was 30 a minute. The accessory muscles of

respiration were called more and more into play as the intoxication progressed, inspiration becoming more and more difficult and finally ceasing quietly when the muscles refused to function any longer. Cyanosis was observed in all cases as respiration weakened and the end approached. Thirst, vertigo, abdominal pain and diarrhea were absent in all cases.

The pulse remained of good volume and good quality throughout, although somewhat rapid and variable in rate. The highest rate recorded was 120 a minute. The temperature reaction was not remarkable, 102.4 F. being the highest recorded, and this followed the intravenous injection of antitoxin. A leukocyte count was made on only one patient, and this was found to be 10,600; the differential count was not abnormal. A lumbar puncture on the same patient revealed nothing other than somewhat increased pressure. The urine was negative except for a very few pus cells found in three of the four patients whose urine was examined.

TREATMENT

Elimination, stimulation and antitoxin were the fundamental bases of treatment. Stimulants, such as strychnin sulphate, atropin, camphor-in-oil, digitalis and coffee enemas were administered as it seemed advisable. Inhalation of oxygen was also used for short periods. Gastric lavage was performed as soon as the patient reached the hospital. Cathartics, for the most part, could not be swallowed. Magnesium sulphate and croton oil, when introduced through the stomach tube, brought no results. High colonic enemas usually brought good results. Nutrient enemas were also used, for the patients had difficulty in swallowing even liquids. Warm blankets contributed much to their comfort.

Antitoxin was not available until four patients were dead and one other was so far gone that he was past aid. This left only one patient, exhibiting definite symptoms, to whom the serum was administered. This patient was Dominick, aged 46. At the time the antitoxin was given, just forty-eight hours after the onset of symptoms, he was presenting the following manifestations of the disease: dimness of vision, diplopia, ptosis of both eyelids, great difficulty in speaking, inability to swallow, much glairy, tenacious sputum in the throat, great prostration and weakness, profuse perspiration, and respiratory difficulty. Twenty-five c.c. of serum obtained from Professor Graham of the University of Illinois were injected intravenously at 7:15 p. m. At 8:30 p. m. there was no apparent change in his condition. At 9:30 p. m. the temperature, pulse and respiration were recorded as 102.4 F., 124 and 30, respectively. The patient grew gradually weaker and ceased to breathe at 10:11 p. m., three hours after the antitoxin was administered.

Lena, the 9 year old daughter who ate one olive, was given two intravenous injections of 15 c.c. each, about twelve hours apart, of an antitoxin received from the Bureau of Animal Industry at Washington, D. C. As mentioned in the case history, it does not seem possible to state that she was presenting definite and clear-cut symptoms. Such symptoms never did develop, but to what degree the antitoxin was responsible for their failure to develop will probably never be known. It is not improbable that symptoms would not have developed if no antitoxin had been administered. Joseph, aged 7, was given one 15 c.c. intravenous injection of the same serum, merely as a prophylactic measure, for

1. Jennings, C. G.; Haass, E. W., and Jennings, A. F.: An Outbreak of Botulism, *J. A. M. A.* 71:77 (Jan. 10) 1920.

at that time there was some uncertainty as to whether or not he had partaken of any of the olives.

Taken all in all, the serum therapy was inconclusive. The serum administered to Dominick was probably given too late to expect favorable results. Furthermore, the serum administered was not prepared from a homologous strain of *B. botulinus*, a fact that would render it ineffective in this case. As stated above, the Graham antitoxin failed to protect laboratory animals against the toxin present in the olives. The serum administered to Lena, presumably derived from a homologous strain, cannot be said definitely to have aborted the development of the disease.

THE EYE AS A PORTAL OF INFECTION IN RESPIRATORY DISEASES *

H. J. CORPER, M.D.

AND

J. J. ENRIGHT, S.B.

DENVER,

The main channel of infection in respiratory diseases, and especially in pulmonary tuberculosis, has confused scientific men for a long time. An effort to avoid infection, especially in the acute diseases, has led to the introduction of many methods of protection, the latest of which is the gauze mask. As complicated as this problem has been in the study of the acute respiratory diseases, it has proved even more baffling and confusing in pulmonary tuberculosis, which disease accounts for at least three fourths of the deaths attributed to the tubercle bacillus. Much of the confusion is of course due to the improper comprehension of the problem at hand and the application of impractical methods of experimentation and conclusions drawn therefrom. Thus have been overemphasized at intervals prenatal infection, alimentary infection and other phases.

The problem that confronts us in the prophylaxis of pulmonary tuberculosis, though differing slightly, is practically the same as that in the acute respiratory diseases. We have to deal in both cases with organisms highly virulent¹ and specific or parasitic for the host, taking hold at the least provocation and producing clearly defined and characteristic pathologic changes, in contradistinction to those produced by the more saprophytic micro-organisms, which occur widely distributed in nature or which cause spontaneous disease in other species.

MODE OF INFECTION IN TUBERCULOSIS

Controversy has revealed diverse opinions regarding the exact portal of infection in pulmonary tuberculosis. Koch in 1884 maintained that tubercle bacilli entered the lungs with the inspired air and produced their lesions wherever they came to rest in the lungs. This view found almost universal acceptance for many years, and the dispute centered about the question as to whether dry and pulverized sputum (Cornet), or fluid droplets (Flügge) freshly expelled from the mouths of phthisical patients, play the more important part in propagating the disease. As a matter of historical interest it may be noted that shortly after the

rediscovery of the infectious nature of tuberculosis by Villemin, Chauveau in 1868 held that the alimentary canal might be the portal of entry in tuberculosis even more frequently than the air passages, an idea probably made evident by the large percentage of ingestion tuberculosis from bovine sources in those days. In 1904, von Behring uncompromisingly maintained the intestinal origin of pulmonary tuberculosis irrespective of age. Calmette and Guérin² in 1905 strongly supported this theory, though they did not agree with von Behring's statement that such infection occurs commonly in infancy. On the contrary, they believed that the lymphatic glands are more permeable in the adult than in the child, and that infectious micro-organisms may pass through them from the intestines to the lungs by way of the thoracic duct. To add to the confusion of this entire problem is the rise of the theory of latency or the residence of tubercle bacilli in the lymph glands and tissues free from all anatomic changes, as maintained by Baumgarten. Such latency has been recently observed by Wang,³ who found bacilli in three of thirty-two cases studied. He reviews the literature, but in all of the cases reported the time element in man is impossible of determination and Wang found that tubercle bacilli could be latent in guinea-pigs as long as 104 days (a comparatively short time of study for enlightenment in this problem).

THE EYE AS A PORTAL OF INFECTION

In considering so important a problem as the avenue of infection in pulmonary tuberculosis, it is conceivable that the question resolves itself not so much into producing effects at the expense of practicability as to considering the problem from the standpoint of facts. For a proper interpretation of facts the available data seem still to be lacking in definiteness, since dosage and the possibility and repetition of infection have been left entirely out of consideration. In the same manner a consideration of the eye as a channel of infection had been entirely neglected until Maxcy⁴ recently demonstrated that this might be one of the least protected regions of the body, giving access to pathogenic micro-organisms by droplet infection, especially from man to man. He found that *B. prodigiosus* introduced into the conjunctival sac can be recovered from the nose in five minutes, from the throat in fifteen minutes, and from the stool in twenty-four hours. With the mouth and nose protected by gauze, organisms were found in the nose and nasopharynx after droplet spraying at a distance of from 3 to 4 feet.

Maxcy states that from the nasopharynx the micro-organisms may follow one of three courses: 1. They may pass outward through the mouth with the sputum. 2. They may be carried into the larynx and reach the lower respiratory tract. 3. They may be carried downward into the esophagus with the swallowing movements, and perish in the intestinal canal or be excreted with the feces. He says that the latter is probably the most frequent course, as he obtained the bacilli in one of three subjects whose stools were tested.

A number of points of direct interest in the problem of the eye as an avenue of infection were left unsettled by Maxcy. These factors seemed worthy of further investigation: whether the micro-organisms really

ever reached the respiratory tract below the epiglottis and vocal cords and how long they remained there; what course the micro-organisms followed after instillation in either eye; how long they persisted in the nose, pharynx or larynx (the studies reported by Maxcy were of only thirty minutes' duration); and since it has been suggested, though not authentically demonstrated, that micro-organisms can enter the lungs by way of the intestinal tract in experimental animals, whether this could occur in man. It was with a view to corroborating and elaborating the work initiated by Maxcy that the experiments to be described were performed.

EXPERIMENTAL DATA

The experiments were carried out on patients with pulmonary tuberculosis who were capable of expectorating (lung) sputum. These people were chosen for the twofold purpose of obtaining satisfactory pulmonary material and also with a view to using patients with a respiratory system of reduced protective mechanism such as may occur acutely at any time in any person but not often in a manner available for satisfactory experimental purposes.

Time Factor.—In order to gain an idea of the rate of appearance and disappearance of the micro-organisms from the nose and various parts of the pharynx after eye instillation, a series of seven cases were thus tested with the results given in Table 1.

TABLE 1.—APPEARANCE AND DISAPPEARANCE OF *B. PRODIGIOSUS* FROM THE NASOPHARYNX AFTER EYE INSTILLATION

Location	—Appearance—		—Disappearance—	
	Earliest	Latest	Earliest	Latest
Nose	5 min.	15 min.	45 min.	2¼ hrs.
Pharynx	10 min.	15 min.	1½ hrs.	2¼ hrs.

A brief survey of this table indicates that *B. prodigiosus* appears and disappears from the nose and throat after eye instillation with fair regularity and within a definite time in different persons.

TABLE 2.—DISTRIBUTION OF *B. PRODIGIOSUS* IN THE MOUTH AFTER RIGHT EYE INSTILLATION

Location	Time Case	Interval after		Instillation in		Hours
		½	1	1½	2	
Hard palate	St. J.	—	+	—	—	—
	Y	+	—	—	—	—
Uvula	St. J.	—	+	+	—	—
	Y	+	+	+	+	—
Right tonsil	St. J.	—	+	+	—	—
	Y	—	—	—	—	—
Left tonsil	St. J.	—	—	—	—	—
	Y	+	+	+	+	+
Posterior nasopharynx	St. J.	+	+	+	+	—
	Y	+	+	+	+	—

Course of Micro-Organisms.—In order to determine whether the micro-organisms instilled into the eye follow a definite course, a suspension of *B. prodigiosus* was dropped into the right eye, and various parts of the nasopharynx were tested with the results shown in Table 2. An examination of this table reveals the tendency of the micro-organisms to follow definite paths. If instilled into the right eye the organisms are found on the right side of the nasopharynx and on the right tonsil, while the left side is free from them, as are also the anterior portions of the mouth. Instilla-

tions of strong solutions of argyrol into the eye were also found to follow a similar definite course in the nasopharynx.

The direct determination of the presence of micro-organisms in the trachea and on the vocal cords, which might indicate a downward passage into the lower

*In these cases the sputum was negative before the pharynx.

respiratory tract after eye instillation, is admittedly difficult, so that a number of procedures were employed for this purpose. It would be unreasonable to expect the determination of the presence of *B. prodigiosus* in the washed sputum itself, and their presence in the unwashed sputum, especially while the nasopharynx was still positive, is obviously open to criticism. There were two other procedures to be considered: the passing of a tube into the trachea, obtaining through this tube a swab of the trachea and vocal cords, and the examination of the (lung) sputum after the nasopharynx and mouth were proved negative by careful and repeated examinations.

A series of ten cases were examined by passing a metal tube into the trachea from four to six hours after the instillation of *B. prodigiosus* into the eye. The nasopharynx was negative for *B. prodigiosus* in these cases after about two hours. It was found that only a small area could be thus swabbed; but two of the ten cases revealed positive cultures from the vocal cords, one within six hours, and the other four hours after eye instillation. In a series of twenty cases the nasopharynx and sputum were examined to determine whether the sputum was positive for *B. prodigiosus* after eye instillation for a longer period of time than was the nasopharynx. The time of appearance of the last positive cultures from the nasopharynx and pharynx and from the sputum in the twenty cases is given in Table 3.

Of the twenty cases studied, there were seven cases, or 35 per cent., in which the lung (sputum) specimens were positive on repeated examination after the pharynx was negative. If these seven cases are considered, the lung specimen was positive on an average of 0.6 hours (minimum, one-quarter hour; maximum, one hour) after the pharynx was negative on repeated examination. One case in the series was of interest because of the fact that a definite positive culture of *B. prodigiosus* was obtained from the sputum one week after the instillation into the eye, the pharynx being repeatedly negative in the interval following the first two hours and also at the time of obtaining the positive culture from the sputum. Three other

cases, observed through an interval of nine days after eye instillation, gave negative sputums for *B. prodigiosus* after the initial few hours following instillation.

DISTRIBUTION AFTER INGESTION

The study of the distribution of *B. prodigiosus* after ingestion was divided into the persistence of the organism in the mouth, the appearance in the sputum, and the appearance in the feces after ingestion. In none of the cases shown in Table 4 was *B. prodigiosus* found in the sputum during the first two hours after the mouth and pharynx were negative.

TABLE 4.—PERSISTENCE OF *B. PRODIGIOSUS* IN THE MOUTH AFTER ORAL INGESTION, IN HOURS

Number of Cases	Time of Persistence		
	Shortest	Longest	Mean
11	4¼	5	4¾

In four cases the nose was examined for *B. prodigiosus*, and in no case were the organisms found within one hour after oral ingestion, while the mouth and pharynx were positive during this time.

In a series of ten cases, *B. prodigiosus* was given by mouth and the sputum and feces were examined after six hours and at daily intervals for ten days. In none of these cases was a positive culture obtained from the sputum; the organisms were recovered from the feces in only two of the ten cases during the first twenty-four hours, after which no more positives were obtained.

TABLE 5.—EFFECT OF HYDROCHLORIC ACID AND HYDROCHLORIC ACID AND PEPSIN ON THE VIABILITY OF *B. PRODIGIOSUS* IN VITRO

Exposure at 37 C.	Concentration of Hydrochloric Acid											
	Alone (Normal Per Cent.)*						With 0.2 Per Cent. Pepsin in Addition					
	0	0.5	1.0	1.5	2.0	2.5	0.0	0.5	1.0	1.5	2.0	2.5
5 min.	+	+	+	+	—	—	+	+	+	+	+	—
15 min.	+	+	+	+	—	—	+	+	+	+	+	—
25 min.	+	+	—	—	—	—	+	+	+	+	+	—
40 min.	+	+	—	—	—	—	+	+	+	+	+	—
60 min.	+	+	—	—	—	—	+	+	+	+	+	—
2 hr.	+	+	—	—	—	—	+	+	+	+	+	—
3 hr.	+	+	—	—	—	—	+	+	+	+	+	—

* One per cent. normal acid is equivalent to 0.0365 per cent. by weight of hydrogen chlorid, and the other figures are in proportion.

In order to find a possible explanation for the inability to recover *B. prodigiosus* from the feces after the ingestion of large amounts of the culture, the effect of various concentrations of hydrochloric acid and of a mixture of pepsin and hydrochloric acid on suspensions of the bacilli was studied with the results given in Table 5. An examination of this table reveals that the cultures of *B. prodigiosus* used in these experiments are highly susceptible to the action of hydrochloric acid, alone or in the presence of pepsin, 0.07 per cent. by weight of hydrochloric acid killing within five minutes.

SUMMARY

The eye must be considered as one of the important portals of infection in respiratory diseases, and, although the greater part of the infectious material entering by way of the eye is subsequently swallowed and passes into the gastro-intestinal tract, a small but definite portion of it finds its way into the larynx and trachea, where it may persist even as long as a week (as was noted in one case studied).

In its passage from the eyes, the infectious material traverses a definite channel dependent on which eye it has entered or into which it has been introduced. Infectious material that is ingested is far less likely to enter the respiratory tract than that entering by way of the eye or nose.

MATERNAL MORTALITY

C. HENRY DAVIS, M.D.

MILWAUKEE

There is a general impression among physicians that there has been a great improvement in maternal mortality during the past half century. This impression is based on the present favorable maternal mortality in hospital and dispensary services, and not on a comparison of mortality and birth statistics.

In 1917, Grace L. Meigs¹ made a careful study of maternity mortality from all conditions connected with childbirth from the available records of the United States and certain other countries. In answer to the question, Is the death rate from childbirth falling? she says (page 17):

According to the evidence available, these death rates are apparently not decreasing. During the twenty-three years ending in 1913, in this country no definite decrease in the death rate from the diseases caused by pregnancy and confinement can be demonstrated; nor can any decrease in the death rate from puerperal septicemia be shown.

She says further of the deaths from diseases of pregnancy and the puerperal state (page 22):

In order to make possible a comparison of the death rate from these causes for fifteen foreign countries with those for the United States, an average rate has been computed for the years 1900 to 1910 for each of the countries, using the same method as that in use in the United States. When the sixteen countries studied are arranged in order, with the one having the lowest rate first, the death registration area of the United States stands fourteenth on the list. Only two countries, Switzerland and Spain, have higher rates; many of the countries, however, show rates differing but little from that of the United States. Markedly low rates are those of Sweden (6), Norway (7.8), and Italy (8.9); a strikingly high rate is that of Spain (19.6). [The ten year average for the United States was 14.9 per hundred thousand population (Table 1).]

The death rate from child birth per thousand live births is not available for the death registration area of the United States, but can be given only for the small number of states and cities included in the provisional birth registration area and for one year, 1910. This rate, 6.5, is considerably higher than that for 1910 of any of the countries studied.

However, a birth registration area was established in 1915, and eventually there will be records from which it will be possible to compute our maternal mortality on the basis of the number of live births. A comparison of the birth rate in the birth registration area with the mortality rate in the death registration area for 1915 and 1916 would indicate that in 1915 one mother died in every 164 live births, and in 1916 one for every 152 live births. The ratio in 1910 was one mother for every 154 live births.

During the past thirty years, deaths from many diseases have been reduced to a fraction of their former toll. Between the years 1890 and 1915, the records of the death registration area of the United States

1. Meigs, Grace L.: Maternal Mortality, U. S. Dept. of Labor, Children's Bureau, Miscellaneous Series 6, Bureau Publication 19, 1917.

show that the deaths from tuberculosis per hundred thousand population dropped from 252 to 145.8; pneumonia, from 186.9 to 82.9; diphtheria and croup, from 97.8 to 15.7; diarrhea and enteritis under 2 years, from 139.1 to 59.5; typhoid fever, from 46.3 to 12.4. The death rate from diseases caused by pregnancy and the puerperal state in 1890 was 15.3, while in 1915 it was 15.2. The maternal mortality rate in 1916 was 16.3 per hundred thousand population.

In the face of all available statistics, we are not justified in believing that the average woman is benefited by the advances that have been made in scientific obstetrics during the past half century. Few realize that for all women of childbearing age, childbirth is the second greatest cause of death. For the year 1915 in the death registration area of the United States, there were, among women aged 15 to 45, 29,200 deaths from tuberculosis; 10,134 from childbirth, of which 4,173 were from puerperal septicemia; 8,766 from the various circulatory disturbances; 6,458 from all digestive disturbances; 5,549 from pneumonia, all types; 5,424 from cancer and other malignant tumors; while for these ages syphilis was reported as the cause of death 647 times and gonorrhea 174 times.

Additional data to prove the great danger of pregnancy and labor are given in Table 2, which is based on a medico-actuarial mortality investigation. The table has been modified and rearranged to make it available for general study and comparison with other statistics. This insurance record shows that for all women insured during the childbearing period, the diseases of pregnancy and the puerperal state are the

the family records of 10,000 applicants. The first series of 5,000 showed that one applicant for life insurance in every seventeen reported a mother or sister or both as having died from the immediate effects of childbirth; 1 in 27 from tuberculosis, and 1 in 47 from cancer or other malignant tumor. The second series of 5,000 cases showed childbirth 1 to 17.7; tuberculosis 1 to 29.7, and malignancy 1 to 42.7. In view of the

TABLE 2.—MOST COMMON CAUSES OF DEATH AMONG INSURED WOMEN IN THE UNITED STATES*

Figures not available.

second greatest cause of death; and for all women insured, maternity ties with nephritis and Bright's disease as the fifth greatest cause of death.

A study of these insurance figures suggested that from insurance records additional valuable information might be obtained regarding the frequency with which individual families are affected by death from common causes such as tuberculosis, childbirth and malignant tumors. Through the courtesy of Dr. J. W. Fisher, medical director of the Northwestern Mutual Life Insurance Company of Milwaukee, I have examined

similar ratios in the two series of 5,000 each, it was not considered advisable to give more time to this line of investigation.

The examination of 10,000 family histories as given by applicants for life insurance would seem to indicate that among the class of men who have applied for life insurance during recent years, maternity has been a cause of death in more families than either tuberculosis or malignant tumors. In comparing these figures with figures already given from the actual numbers of deaths based on the causes recorded on the death certificates, it must be remembered that tuberculosis is most frequent and most fatal among the very poor—a class excluded from the life insurance records except as a percentage of applicants may have been born in poverty either in this country or abroad. Another and possibly more important reason for the great frequency of childbirth over tuberculosis arises in the practice of physicians in giving tuberculosis or other general cause on the death certificate of the woman who dies shortly after delivery without reference to the childbirth. The layman, on the other hand, remembers the childbirth and not the cause of death recorded on the death certificate.

The records of large maternity hospitals indicate that most of the deaths from puerperal sepsis are preventable when a rigid surgical technic is employed in the delivery room, and that many of the deaths from other complications of pregnancy, labor and the puerperium are unnecessary. The continued high maternal mortality constitutes a standing reproach to all civilized peoples in general, and to the medical profession in particular.

The teaching of obstetrics has perhaps not kept pace with that of general medicine and general surgery, but for this the teachers of obstetrics are only partially responsible. Obstetrics has always been the most time consuming and at the same time the poorest paid work

a physician undertakes. Comparatively few physicians have specialized in this branch of surgery. Hospital facilities for obstetric cases are most inadequate when compared with those for general surgical or medical cases. Comparatively few hospital interns have any real training in obstetrics. Most physicians in general practice have to handle all types of labor with little training and under the most unfavorable conditions.

The present need in obstetrics is not so much the discovery of the cause of certain rare and obscure conditions, but rather the application of present knowledge. The infection of obstetric patients should be prevented by elimination of the unclean midwife—both male and female. This may be accomplished by systematic and long continued education of the people and the profession. The toxemias of pregnancy should be prevented through careful prenatal supervision. Most of the severe toxemias are preventable. The delivery mortality and morbidity should be reduced to the minimum by ample hospital facilities. There is no longer any question about going to the hospital for even the most simple operation. Why continue the practice of doing obstetric surgery in a home with lack of facilities and questionable asepsis?

SUMMARY AND SUGGESTIONS

1. Mortality statistics show that for women of child-bearing age (15 to 45), childbirth is the second greatest cause of death. The records of life insurance companies show that for all women who are insured under 45 years of age, the diseases of pregnancy and the puerperal state are the second greatest cause of death. Childbirth ties with nephritis and Bright's disease for fifth place as a cause of death among insured women.

2. A study of 10,000 family histories as given by applicants for insurance in the Northwestern Mutual Life Insurance Company shows that one in every 17.3 associates the death of a mother or sister or both with childbirth, 1 in 28.3 with tuberculosis, and 1 in 45 with malignancy. It is believed that a considerable percentage of these deaths from childbirth were recorded on the death certificates as being due to tuberculosis, heart disease, etc., and that the applicant for insurance remembered the associated childbirth and not the cause of death given on the death certificate. Our present mortality records do not show the frequency with which childbirth is a contributing cause of death.

3. The present maternal mortality may be greatly reduced by application of our present obstetric knowledge. Systematic education similar to that used in combating tuberculosis is needed.

4. Increased hospital facilities and nursing service must be provided. The state should furnish assistance in giving poor women the proper care during pregnancy, labor and the puerperium. For the present, more hospital beds may be made available by sending women home by ambulance early in the puerperium and caring for them through an outpatient nursing service.

5. The clinical teaching of obstetrics must be improved. Outpatient services are at present necessary; but as soon as beds are available, these women should all be brought to the hospital for delivery. Students get a midwife idea of obstetrics from the so-called simplified technic used in many outpatient services, and reflect these methods in the continued high maternal mortality. Few interns have an obstetric training comparable with that received in medicine and surgery. They go into general practice, and must meet the emer-

gencies of obstetric practice with the inadequate training received as an undergraduate.

6. Churches could aid greatly in making motherhood safer, if on Mother's Day special collections were taken for the obstetric services of our various hospitals. In addition to the money raised, such a collection would have an educational value by calling the people's attention to the great obstetric needs.

Clinical Notes, Suggestions, and New Instruments

A SIMPLE TECHNIC FOR CONCENTRATING SPUTUM*

STANLEY WOOLLEY, M.D., LOOMIS, N. Y.

Greenfield and Anderson¹ have recently described a simple technic for the sedimentation of tubercle bacilli in the sputum. In brief, this method consists in placing a small amount (5 c.c.) of sputum in a centrifuge tube, adding two volumes of 1 per cent. sodium carbonate in 1 per cent. phenol (carbolic acid), shaking well, and placing in the incubator for from twelve to twenty-four hours. The tubes are then centrifuged for about fifteen minutes and smears made from the sediment after pouring off the supernatant fluid.

The advantages claimed by the author for this method are: (1) rapidity; (2) sterility of sputum when taken from the incubator, and (3) the resemblance of the films to direct smears. They also made controls of their method, using the full technic of Ellerman and Erlandsen for comparison, and report a distinct advantage in the simplified method.

This technic was recently tried out at the Loomis Sanatorium, and with some slight modifications, has been adopted in place of the more cumbersome Ellerman and Erlandsen technic.

The sanatorium uses the standard 4 ounce blue glass pocket sputum flasks ("Cleaneasy") for collecting sputum for concentration or sedimentation. As these are graduated, it is a simple matter to add the required amount of sodium carbonate solution directly to the sputum. The cork is replaced and the contents are thoroughly mixed by shaking. If the bottle is more than one-third full, which is usually not the case, a portion of the contents can be discarded, or treated in the same way in another bottle.

Placing in the incubator (37.5 C.) overnight has generally been found sufficient for digestion. On removal, the bottle is again shaken and the contents poured into a 50 c.c. plain, lipped centrifuge tube. In case there are more than 50 c.c. in the bottle, a sufficient amount is discarded before shaking. These tubes are centrifuged for fifteen minutes in an electric centrifuge, the supernatant fluid is poured off, and smears are made in the usual way.

In comparing the two methods, thirty-seven specimens were examined. After thorough shaking of the sample of sputum, the contents of each bottle were divided: one part was used for the standard Ellerman and Erlandsen (E. & E.) method, and the other for the simplified Greenfield and Anderson (G. & A.) technic. The G. & A. method showed nine positives and twenty-eight negatives, the E. & E. method eight positives and twenty-nine negatives. The results were the same for each specimen by the two methods, with the one exception in which the E. & E. method was negative. Each slide was thoroughly examined by two examiners, and separate records were kept and compared after all slides were scrutinized.

The advantages of the G. & A. method, besides its simplicity and cleanliness, are that the sediment yields better smears and the stained bacilli are more distinct. This is probably because digestion is not quite as complete as in the E. & E. method, but our limited experience seems to show that it is sufficient for all purposes.

Therapeutics

A DEPARTMENT DEVOTED TO THE IMPROVEMENT OF THERAPY.
A FORUM FOR THE DISCUSSION OF THE USE OF DRUGS
AND OTHER REMEDIES IN THE TREATMENT OF DISEASE.

USE AND ABUSE OF CATHARTICS *

(Concluded from page 461)

RHUBARB

Rhubarb¹ might be called the "constipating purge"; it presents a remarkable combination of constipating and purgative action, since it contains tannic acid and a resinous body, which, on hydrolysis, yields various purgative anthraquinon derivatives (rhein, emodin, chrysophanic acid, etc.). The latter may also exist partly free. In addition, this drug contains a large amount of calcium oxalate, which accounts for its "grittiness" when chewed.

MODE OF ACTION AND INDICATIONS

With small doses (up to 0.3 gm., or 5 grains), the astringent action predominates; with gram doses (15 grains or more) the purgative action is brought out, a mushy evacuation resulting in from six to ten hours, followed by a greater tendency to constipation than is the case with most other purgatives. When used in sufficiently large doses to be a reliable cathartic, rhubarb is a distinct irritant to the intestine; hence it is contra-indicated in such conditions as enteritis or mucous colitis.

Authorities differ regarding the use of rhubarb in chronic constipation. Some consider it especially indicated in this condition, because—as is the case with other anthraquinon cathartics (cascara sagrada, senna, aloes)—habituation does not readily occur. Others, and with greater cogency of reason, condemn rhubarb as one of the worst of all cathartics in chronic constipation, because of its tendency to leave constipation as an after-effect. We may safely conclude that chronic rhubarb purgation is a misuse of the drug. It surely cannot cure chronic constipation; and it might make it worse.

Rhubarb is claimed to be especially indicated in those cases of delicately poised enteric function, occasionally found in feeble women and children, characterized by a tendency to diarrhea following the use of any other purgative. Rhubarb knows when to "stop." The introduction of such nonirritating physical laxatives as liquid petrolatum and agar, which cannot cause excessive action, has rendered rhubarb much less important in such cases.

The chief use of rhubarb is in the milder diarrheal disturbances, especially of infants and children. On the other hand, in the severer diarrheal disorders, when there is actual inflammation of the intestine, rhubarb would be contraindicated because of the possibility of its acting as an irritant. When the intestinal tract contains curds or other unsuitable or indigestible food, which produces colic and diarrhea in the course of "nature's" efforts at evacuation of the irritant, rhubarb

is a remedy *par excellence* to reinforce the salutary tendency to evacuation, and to antagonize, by its astringent action, an excessive prolongation of the diarrheal discharges. For this purpose the *aromatic syrup of rhubarb* is usually administered, and with good reason. Here is a pharmaceutical masterpiece in efficiency of drug disguising. Children delight in taking it. It is so weak a preparation—representing only 3 per cent. of the drug—that it can be given in teaspoonful doses even to infants. For adults it is too feeble in action. The following is Kerley's² schedule of dosage:

DOSAGE OF AROMATIC SYRUP OF RHUBARB

6 months	4 c.c. (5 i)
18 months	8 c.c. (3 ii)
3 years	12 c.c. (3 iii)
5 years	16 c.c. (3 iv)

For children, this is the rhubarb preparation to be preferred to all others, unless the sugar contained in it should render it objectionable, as in excessive intestinal fermentation. In such cases, an equivalent amount of the aromatic tincture of rhubarb, of which the syrup contains 15 per cent., might be substituted; and benzo-sulphinid (saccharin) used for sweetening, as in this prescription:

	Gm. or C.c.
R Benzosulphinid	0/03
Sodium carbonate	0/03
Aromatic tincture of rhubarb.....	4/50
Water	30/00
Dosage same as that of the syrup.	

This drug has the reputation of being "good for the stomach." It would no doubt be as difficult to bring objective proof for this action as it is for that of other so-called stomachics. Its not unpleasant bitter, aromatic taste and its astringent effect would entitle it to rank among the astringent bitters were it not for its purgative properties. This combination of qualities possessed by it renders rhubarb superior to other astringent bitters in some cases of dyspepsia complicated with constipation. For this purpose, owing to the stomachic qualities of the alcohol contained in them, one of the tinctures, the tincture of rhubarb (20 per cent., spiced with cardamom) or the more pleasant aromatic tincture (also 20 per cent., flavored with cinnamon, clove and nutmeg) would be employed in teaspoonful doses—more or less, according to the effect on the bowels—taken in a little water half an hour before meals. This treatment is, of course, suitable only in "atonic" conditions, and would be contraindicated by a state of excessive irritation or irritability.

SIDE EFFECTS

As the rhubarb stools have a "bilious" appearance due to the presence of the coloring matters of rhubarb, it was formerly classified as a cholagogue, and special indications were constructed for it based on this supposed action on the liver. We now know that it is not a real cholagogue, and that whatever benefits are obtained from its use in liver disturbances are due to its cathartic action. It must be remembered that, owing to the chrysophanic acid it contains, rhubarb imparts to the urine a yellowish color, which may lead one to suspect the presence of icterus. This urine may be distinguished from that of jaundice by the fact that it becomes purplish red on the addition of an alkali. Rhubarb renders the milk of nursing women laxative to the child. The drug has been known to cause macular, vesicular and even hemorrhagic eruptions, though such effects are rare.

2. Kerley, C. G.: The Treatment of the Diseases of Children, Philadelphia, W. B. Saunders Company.

* This article, the nineteenth, concludes the series on the "Use and Abuse of Cathartics." These articles, with revision and additions, will shortly be published in book form.

1. Rhubarb is the rhizome of an Asiatic plant, related to but by no means identical with the "rhubarb" or "pie-plant," the juicy stems of which we use in cookery. Eating of these has, therefore, merely the laxative value of cellulose food, and will, of course, not give one the purgative action of the official rhizome.

METHOD OF ADMINISTRATION

For solid administration forms, powdered rhubarb is to be used. The *extract of rhubarb* is undesirable, as it is unreliable in action. The active principles are so easily injured by heat that the extract may even be less efficient than the powdered root.³ Soap forms a good excipient for rhubarb pills. This prescription might serve as example:

	Gm. or C.c.	
R Rhubarb, powdered	6/0	gr. xc
Soap, powdered	2/0	gr. xxx
Water.....enough to make a mass	1	
Mix and divide into 30 pills.		
Label: One or two after each meal.		

Each of these pills contains only 0.20 gm. (3 grains) of rhubarb; and more than 0.30 (5 grains) could hardly be given in pill form, on account of the necessary limitation in the size of pills. Hence, when larger doses are required, the powder form must be employed, though the powder might be disguised by enclosing it in cachets, each of which may be made to contain up to 0.60 gm. (10 grains) of the powder. Some persons actually enjoy chewing rhubarb; and little cubes of the rhizome are on the market, especially suitable for this purpose.

RHUBARB AND ALKALI

The addition of alkali prevents precipitation when an alcoholic preparation of rhubarb is mixed with water. This is the reason for the presence of a small amount of potassium carbonate in the syrup of rhubarb. There are numerous other compound rhubarb preparations, however, in which alkali is used for synergistic or for cooperative action.

Compound rhubarb powder, also known as Gregory's powder, is a mixture of:

Powdered rhubarb	25 gm.
Magnesium oxid	65 gm.
Jamaica ginger	10 gm.

- We have here the evacuant action of the rhubarb, which acts chiefly as stimulant to peristalsis, reinforced by the laxative action of the magnesium ion, which acts by retaining fluid in the bowel. In addition to this, the antacid action of the magnesium oxid is of value in excessive intestinal acidity, which is frequently present in the summer diarrheas of infants and children. The dose of this powder for an adult would be from 2 to 4 gm. (one-half to 1 dram); for a child 2 or 3 years old, from 0.3 to 0.6 gm. (5 to 10 grains). This powder is, however, far from being palatable. Adults will take it, but children only with protest and often only after a struggle. In this connection, two axioms on children's medication might be laid down:

1. A struggle in administration sometimes does more harm than the medicine can do good.
2. The more we know about medicines, the less offensive is our medication.

That it is not necessary to inflict Gregory's powder on the sensitive palate of a child is shown by a prescription that offers all the effects obtained from the powder in an actually delicious form:

	Gm. or C.c.
R Magnesia magma	30
Aromatic syrup of rhubarb.....	30
M. Label: Teaspoonful every two hours.	

The proportion of the ingredients, size of dose, and frequency of repetition of dose may, of course, be varied to suit the individual case. The previously described saccharinated substitute might be used

instead of the syrup in cases in which sugar would be contraindicated.

"*Rhubarb and soda*" is quite a popular stomachic remedy, and deservedly so. It is a veritable gastric polychrest, combining the previously detailed effects of rhubarb in dyspepsia with those of baking soda, which is probably the single most efficient temporary remedy against gastric distress. Rhubarb and soda tablets are marketed by various manufacturers. They are the most convenient form for administration of this remedy to the average dyspeptic. This prescription might be useful:

	Gm. or C.c.	
R Powdered rhubarb	10	3 iiss
Sodium bicarbonate	30	3 i
Oil sugar of peppermint (N. F.)	30	3 i
Mix and divide into 30 powders.		
Label: One, in hot water, after meals as required.		

The oil sugar might be omitted for those who dislike sweet, or for patients with whom sugar disagrees. The 0.60 c.c. of oil of peppermint contained in the oil sugar (2 per cent. according to a general formula in the National Formulary) might be incorporated with the other drugs. For patients who dislike the flavor of peppermint—and there are such—oil of fennel, oil of anise, or any other volatile oil desired might be substituted. Instead of being divided into doses, the powder might be dispensed in a box and the patient directed to take a level or a heaping teaspoonful, as required. This preparation is therapeutically as efficient as, and pharmaceutically much superior to, the old and now no longer official *mixture of rhubarb and soda*, at present embalmed in the National Formulary under the title of "*Compound Rhubarb Mixture*." The manner in which the extemporaneous preparation may be modified, as indicated above, to suit the needs and idiosyncrasies of the patient proves the undesirability, so often noted in other instances, of ordering a ready made "hand-me-down" mixture.

TREATMENT OF LARVA MIGRANS, OR
CREEPING ERUPTION

DR. R. R. KIME, Lakeland, Fla., writes: In *Queries and Minor Notes* (THE JOURNAL, March 8, 1919, p. 748) there was a short discussion on the treatment of larva migrans, or creeping eruption. Most of the methods of treatment presented are painful and uncertain in results. I would suggest a simple, efficient, quick, easily applied remedy, consisting of salicylic acid, 10 grains, for young children, or salicylic acid, 20 grains, to collodion, 1 ounce, for older children. If this is painted well over the eruption, especially at the points of migration, twice daily, the eruption will soon disappear. The collodion obstructs migration and the salicylic acid destroys the larva.

Faræus' Sedimentation Test for Pregnancy.—Faræus noticed that the blood of a pregnant woman allows more sedimentation of erythrocytes than the blood of the non-pregnant. He uses a tube 0.01 cm. in diameter, and mixes in it 8 c.c. of blood with 2 c.c. of a 2 per cent. solution of sodium citrate, and sets it aside for an hour. If the sediment of the corpuscles then reaches only to a height of 1 cm. or less, the woman is not pregnant as, with blood from a pregnant woman, the sediment was always found extending above the 1 cm. mark. Hauch stated at the recent French Gynecologic Congress at Brussels that this test is being used considerably in the Scandinavian countries, and that negative findings could be relied on, but that positive findings were noted sometimes in certain diseases as well as in the pregnant.

3. For the same reason the use of the fluidextract of rhubarb is very limited.

AMERICAN FOOD HABITS AND HEALTH

Changes in the food habits of large groups of persons may be brought about by necessity and likewise by altering customs and food preferences. Conditions determined by the war and consequences arising from it have enforced pronounced changes in the dietaries of thousands. What the outcome of this necessary response to the exigency of food situations may be is now being exemplified in the effect of the innovations on the health of the affected nations. Scurvy, beriberi and war edema are conspicuous illustrations of the extreme effects brought about by necessity, that is, by actual shortage of certain foods or by their high cost. A few months of deprivation may suffice to send deficiency diseases broadcast among people previously living in good health and working efficiency.

The other category of change in food habits by which new dietary customs come into vogue and older choices lose their popularity is slower in becoming manifested. The more permanent revisions of food preferences are not ordinarily created by famine, war or pestilence. They develop slowly, like other changes in styles; nevertheless they do arise, despite the fact that many persons assume that our food practices are perennially the same. Recently the Office of Home Economics in the United States Department of Agriculture¹ completed a comparison of the foodstuffs purchased by 500 families with the amounts of the same foods purchased by 400 families about twenty years ago. The outcome shows that the amount of meat in the diet has decreased about 8 per cent., and grain products about 11 per cent., while dairy products have increased about 6 per cent.; vegetables, 4 per cent., and fruits, 8 per cent. The average amount of meat and fish supplied in the diet in the 500 studies was about 6 ounces daily per man; dairy products, 16 ounces; grain products, 13 ounces; vegetables, 16; fruits, 9; sugar and syrups, 3, and fats, 2 ounces.

The statistics indicate, so far as such broad generalizations which deal with the quantity of nutrients rather

than the special qualities of the foods can be depended on, that the "average" diet of such groups is adequate. The use of milk increased up to 14 ounces a day in the period under consideration. This is scarcely more than one-third quart a day; and since the amount of milk did not increase in accordance with the greater number of children in the families studied, the undervalued importance of milk in the dietary still deserves to be emphasized to the American public. Few of the dietaries were seriously below the accepted standards for the more important mineral ingredients required, namely, iron, calcium and phosphorus. The average dietary is more likely to be deficient in iron than in the other elements mentioned. The data indicate that milk and other dairy products supply the greatest percentage of calcium; vegetables and grain products, the greatest percentage of iron; and dairy and grain products, the greatest amount of phosphorus, and in each case at the lowest cost.

THE CONSEQUENCES OF BURNS

The pathogenesis of the severe symptoms, often ending in death, which may follow burns has long been a matter of speculation. The widely unlike character of the phenomena involved makes it more than probable that differences in the degree of injury are attended by a variety of untoward consequences not necessarily dependent on a common cause. Thus, in burns of the first and second degree there is little, if any, actual destruction or disintegration of the tissues, the reaction being more nearly of a severe inflammatory character. On the other hand, in the severe damage of burns of the third degree, when subcutaneous cellular tissues are actually destroyed, unusual chemical products may be generated, and their possible deportment in the organism must be taken into account. It is easy to understand how local symptoms arise in the case of burns; but the nature of the less frequent but more aggravated general phenomena, with their remote effects, has been more puzzling.

An unusually large number of observations on a group of persons more or less severely burned in a munition factory near Frankfort¹ has afforded an opportunity to test, on a considerable scale, the validity of some of the theories that have been advanced to explain the consequences of burns. The theory of Sonnenburg,² which attributed death to a reflex depression of the vasomotor tonus, failed to receive support from these clinical cases. Vasomotor shock was not a common manifestation. Marked changes in the blood, reported by a number of observers, have been emphasized as factors of primary significance. Alterations in the form of the red corpuscles with hemoglobinuria,

and particularly a loss of water from the blood accompanied by an increase in the number of erythrocytes amounting sometimes to 4,000,000 per cubic millimeter, are on record. In the Frankfort victims hemoglobi-nuria, which is often regarded as an almost specific symptom of severe superficial burns, was by no means always present. The formed elements of the blood were considerably altered in several instances, but the most striking finding was the enormous increase in the number of leukocytes, which reached 50,000 per cubic millimeter in one case. Whatever the significance of such changes in the blood picture may be, they cannot be regarded by themselves as of sufficient moment to account for the severity of the symptoms exhibited by badly burned patients. In any event it is unlikely, to say the least, that the altered red corpuscles so often observed after burns could produce by thrombosis or embolism those lesions which have been observed at necropsy.

The most probable hypothesis of the pathogenesis of burns still remains unchallenged. It looks on the clinical manifestations, such as delirium, hemoglobi-nuria and albuminuria, as well as on the anatomic find-ings, as the outcome of a profound intoxication.³ How-ever obscure the nature of the hypothetic poison still is, there are many hints that it may be allied to those prod-ucts which are concerned in so-called anaphylactic shock. One thinks, first of all, of protein derivatives that might arise through the destruction of the tissues at the site of injury. It is no longer a new conception to assume that the organism may be sensitized by chemical compounds arising through abnormal reac-tions in its own tissues. Vogt³ has summarized this view in suggesting that death following immediately on a burn may be due to shock, while delayed death is the outcome of an intoxication. The poison is gen-erated in the area of tissue destruction, and by its continued absorption and distribution leads to a sensi-tization of the body which, in turn, permits subsequent death by anaphylaxis.

Corresponding with the views just formulated, the detection of foreign toxic products in the urine has been reported after severe burns as well as following anaphylactic seizures. Becky and Schmitz¹ assert the presence of a protein of unidentified character in the urine of the Frankfort patients, and they confirm the previous reports concerning the enhanced toxicity of the urine for mice. Bearing in mind the fiasco of earlier studies on "urotoxic coefficients," and the unfortunate confusion which they caused in discus-sions on "autointoxication," we may well hesitate to embody such evidence in any theory of intoxication after burns. The essential features of the possible production of poisons in burns are by no means invali-dated, even if the current evidence is not yet conclusive.

From the standpoint of treatment it cannot be too strongly emphasized that something far more serious and threatening than the mere disintegration of local-ized areas of tissue must be taken into account. A profound systemic intoxication may be involved.

"UP FROM INSANITY"

Newspaper medicine contributes much to the gaiety and insouciance of medical life, as may be seen by the frequent quotations from the lay press in our Tonics and Sedatives. There is some excuse for the ephemeral dailies whose reporters can hardly be expected to be familiar with the elaborate technical terms of medicine; it would be impossible to employ a medical censor to examine the hourly output of world news. It amuses us if the reporter discusses the interstitial glands, ascribes *Taenia solium* to its proper place in brain anatomy, credits some surgeon with the clever removal of the Ethiopian tubes, and eyes us as he writes with a scarcely perceptible movement of the alligator super-cilli. But it is a matter of concern when a dignified monthly periodical, with weeks and often months for consideration of its manuscripts, gives publicity to med-ical material which is unproved, misleading, untrue or sensational. It should not be difficult to have any med-ical essay scrutinized by expert physicians before publi-cation.

The November issue of the *Atlantic Monthly* con-tained an article entitled "Up from Insanity" by E. J., purporting to be the experiences of one who had been insane and had recovered. The editor of the *Atlantic* is at pains to say of the author that "his life has been precisely as described in his revealing narrative. He could not be so frank and sign his name; but that name is known to the editor. The paper has been the subject of much correspondence, and with the author's consent pains has been taken to verify many of the facts. The *Atlantic* has entire confidence that the story is genuine down to the smallest detail." The editor thus claims to have taken pains to verify many of the facts, and says that the story is genuine down to the smallest detail. But there is one fact, one small detail, that the editor has not authenticated; that is, as to whether the writer of the article has ever suffered from insanity. It is, of course, a small detail, but it should not have been overlooked.

There is no evidence in the article itself that "E. J." ever did suffer from insanity; and since the editor offers us no proof of the fact, it would seem that a very essential element in the story is lacking. On the other hand, there is in the article considerable evidence that the writer was not insane. After a harrowing description of an episode intended to be the real "thriller" of this sensational paper, the writer (on his way to hunt big game in Africa) consulted a "celebrated New York specialist" who told him he had only six

3. Bardeen, C. W.: Johns Hopkins Hosp. Rep. 7: 137, 1898. Eyff: Centralbl. f. d. Grenzgeb. d. Med. u. Chir. 4: 428, 1901. Pfeiffer: Virchows Arch. f. path. Anat. 180: 367, 1905. And particularly Vogt: Ztschr. f. exper. Path. u. Pharmacol. 11: 191, 1912.

months to live, and his advice "was to go out and hunt and roam the world and make the best of the passing hours." As there is no curable form of insanity in which sudden taking off could be predicted, and as any celebrated specialist would have been a little more politic in his prognosis to an insane man, and under such circumstances would have advised a sanatorium for the remainder of his brief career, we are inclined to believe that the specialist did not discover insanity in the patient. But he seems to have made a wrong prognosis, and Time took its revenge. The writer went on the suggested hunting trip to Africa, and on his return he learned that just *six months* after he had left the United States "*that great physician had died—insane.*"

We shall have to be brief with the "thriller" just alluded to: One cold, raw March day, while traveling from village to village in a buggy, as a salesman, apparently, he entered a country store and found as he crossed the threshold that a great change had come over him. He leaned against the counter to keep from falling, was unable to speak, and "grinned diabolically" in attempting to talk to the merchant. The merchant in a kindly and fatherly way helped him back into his buggy, and he drove seven miles in a torrential down-pour to a village inn. The host helped him out, and as he supported him into the house winked at his pals around the stove. The patient grinned "like a Cheshire cat," had lost his power of locomotion, stared at the pals who burst out laughing in his face, finally got to his room, fell across the bed fully dressed and went to sleep, with a vicelike frontal headache. Sometime in the night he awoke, lighted a lamp, looked at himself in the mirror (he describes the "horrible caricature" with reportorial frills) and then became intensely nauseated and violently ill! After closing this description he exclaims: "That, my friends, is insanity, the ultimate curse of God." On the contrary, the description does not fit insanity at all, but is a clinical picture of a condition very familiar to physicians and to laymen in times past—before the days of prohibition. The inn-keeper and his friends around the stove evidently—from the text—made a diagnosis at the time. They laughed. Their diagnosis may have been wrong. It may be that it was a hysterical nervous condition from fatigue and exposure simulating closely intoxication; but the description does not fit insanity.

The picture of himself as drawn by the writer in the article is that of a man now about 42 years of age, who had been at various times a salesman, a wanderer and a reporter. He was a poor mixer, odd, eccentric, shy, morbidly self-conscious so that at one time he wore blue glasses because of this, and given to introspection. In other words, he describes the usual course of an ordinary case—a neurotic individual with a tendency to hypochondriacal self-analysis, self-pity and gross exaggeration of his symptoms.

There is plenty of really good literature written by the insane, either after recovery or during the progress of the disease, and some of it has been of distinct benefit to humanity; for instance, "The Mind that Found Itself," by Clifford Beers—a book that led to the foundation of useful societies of mental hygiene in this country and Canada, and has furthered the welfare of the insane everywhere. Then there is the "Autobiography of a Paranoiac," extracts from which were published years ago in the *Journal of Psychology*, a truly extraordinary self-analysis, written in most excellent style, and a real contribution to psychology. "Up from Insanity" is misleading and sensational, carries no conviction, does no good, and the *Atlantic Monthly* is the last periodical in which one would expect to see such an article.

BOTULISM FROM RIPE OLIVES

For the fourth time within a few months a highly fatal outbreak of botulism due to ripe olives is recorded in our columns. The article on an outbreak of botulism in New York in THE JOURNAL¹ this week follows close on the heels of the report of the Memphis outbreak in our "General News" of last week. These added to the outbreaks at Canton, Ohio, and Detroit make a formidable showing.

Three of the four outbreaks appear to have been traced to one brand of olives, packed in southern California, a fact that we believe should be given wide publicity at this time, even if commercial interests suffer. It seems at all events as if all local health authorities should make systematic attempts to find out whether this particular brand of olives is being distributed within their jurisdiction. It is only the part of prudence and good common sense to make sure so far as possible that olives of this brand are not being "salvaged" and perhaps distributed to scores of small groceries and delicatessen shops throughout the country.

Two particularly disturbing features characterize these later outbreaks, one being that the olives apparently responsible for the New York outbreak were not of the same brand as those causing botulism in Canton, Detroit and Memphis. If it is true that more than one brand of olives is involved in the causation of botulism, the difficulties that public health authorities will have in coping with this menace are measurably increased. It is evident also that the whole ripe olive industry should be subjected to investigation and supervision. Steps in this direction have already been taken, as is also noted in our news columns. Thus far green olives do not seem to have been implicated in the causation of botulism.

The second point about which concern may well be felt is the seeming willingness of unscrupulous dealers

1. Sisco, D. L.: An Outbreak of Botulism, this issue, p. 516.

to sell olives and perhaps other foodstuffs that have been condemned. We are informed that the olives causing death in Memphis were obtained from a store of which the principal business is buying and selling salvaged merchandise. In this case, olives found in a dish on the table at the house where they were served had a very objectionable and pronounced foul odor. In the New York outbreak, a distributing company in New York City refused to put the olives on the market under their label, but the jars were resold by the California olive company that packed them and were shifted about from place to place for some months, many being rejected during their circulation because they were obviously spoiled and unfit for sale. From the information available it does not seem clear that the olives that were eaten in New York had a definitely spoiled odor. The only evidence from those eating the olives came from one victim shortly before death, who stated that he noticed nothing wrong about the odor or taste, and from one 9 year old child, who also noticed nothing disagreeable in taste or odor. Although a half bottle of ripe olives, probably the one that contained the toxin, was found in the home of the victims, no statement is made about the physical condition of these olives.

It seems clear that immediate and drastic warning should be given to dealers regarding the sale of ripe olives showing any signs of spoiling. It is also true that at least until fuller information is available salvaged food, particularly olives, should be regarded with considerable suspicion by the general public.

Current Comment

A PECULIAR SYNDROME ASSOCIATED WITH ADENOMA OF THE HYPOPHYSIS

Hitherto there have been two clear-cut clinical pictures associated with disease of the hypophysis: acromegaly, first accurately described by the French clinician Pierre Marie, and the syndrome described many years later by Fröhlich as dystrophia adiposogenitalis. It has generally been assumed that acromegaly is an indication of hyperpituitarism, while Fröhlich's syndrome is a manifestation of hypopituitarism. The work of American observers, and particularly of Harvey Cushing, has thrown a good deal of light on the subject of disorders of the hypophysis, and has indicated that in addition to these classical pictures certain atypical manifestations may at times be associated with disease of this gland. Reichmann¹ has recently recorded two examples of a third fairly clear-cut syndrome associated with disease of the hypophysis and easily distinguishable from either acromegaly or Fröhlich's syndrome. The prominent clinical features presented by his patients were turgidity and cyanosis of the face, with exophthalmos and dilated pupils; cardiac hypertrophy, with hypertension and bradycardia;

glycosuria, premature menopause, pronounced myasthenia, edema of the legs, and a blood picture showing a decrease in the lymphocytes. In the patient who came to necropsy, the lesion was a chromophil adenoma of the anterior part of the hypophysis, such as has been described by Benda as characteristic of acromegaly. The necropsy disclosed in addition a small thyroid rich in colloid material, and a slight but definite hyperplasia of the suprarenals. There was also osteoporosis in the bones of the vertebral column, and the patient had noted that her stature was gradually decreasing. It is apparent from the pathologic findings in this case that, while the main lesion was in the hypophysis, there was evidence that other glands of internal secretion were involved. The thyroid was smaller than normal, and the suprarenals were somewhat hyperplastic. Indeed, Reichmann had concluded during the patient's life that the syndrome was probably a polyglandular one. Reichmann is of the opinion that the clinical picture presented by these patients is not exceedingly uncommon. It will, of course, require further reports to determine whether this is the case. History has usually shown that the description of a new syndrome is followed by its recognition in various parts of the world, and there is little doubt that other reports on this peculiar condition will appear in the literature if Reichmann's assumption is correct. Since our knowledge of the glands of internal secretion is still very fragmentary, observations of this sort are stimulating both to the clinician and to the laboratory worker.

THE PIGMENTS FOUND IN NERVE TISSUES

The existence of lipochromes—fat-holding or fat-combining pigments—in various parts of the body has long been recognized. The yellow color characteristic of the corpora lutea belongs to the group here referred to. Only in recent years has the chemical nature of some of the lipochromes been more clearly understood. The pigments of milk fats and body fats, of egg-yolk, of blood serum, of the corpus luteum and of other tissues have been identified as belonging to two classes of coloring matter, the carotin and xanthophyll pigments, respectively. We are indebted especially to the work of Palmer and his associates¹ in this country that these carotinoid pigments are now known to represent in many, if not in all cases, merely the lipochromes of plants transferred in the form of animal or human food and incorporated into the animal tissues. Histologists are familiar with a pigment that accumulates in the nerve cells in advancing life and sometimes under pathologic conditions. Of its origin and nature little has been known definitely. Because the pigment has been observed in certain wasting processes, some pathologists have looked on it as originating in the cells through their "wear and tear." As nothing more specific than staining methods has been depended on to determine the identity of the so-called cell lipochromes in most cases, it is by no means certain that the same products have been encountered in every instance.

1. Reichmann: *Deutsch. Arch. f. klin. Med.* **130**:133, 1919.

1. Palmer, L. S., and Eckles, C. H.: *J. Biol. Chem.* **17**: 191 (March) 1914; **23**: 261 (Nov.) 1915; **27**: 27 (Oct.) 1916.

For one case, that of the lipochrome pigment of the nerve cell, however, the researches of Dolley and Guthrie² at the University of Missouri appear to have given a satisfactory answer. They demonstrate that it is a plant carotinoid pigment, derived from the food and incorporated in the cell, but limited to such species as carry carotinoids in the blood serum. Thus, in bovines, the occurrence of lipochrome in nerve cells appears to be customary; in swine, it is absent. Man, who is best known to exhibit lipochrome, is also known to carry carotinoids in his blood serum and to have colored fat. Some investigators have attempted to distinguish a group of pathologic pigments from the true lipochromes by calling them "lipofuscins."³ Dolley and Guthrie² have been able to make pigment appear in or be absent from the nerve cells, according to the method of feeding they employed. When carotinoid-free diets were given, the lipochrome was missed from the nerve cells. They demonstrated that the reactions of the pigment that they could induce experimentally to deposit in the nerve cells was identical in its microchemical tests with the so-called "lipofuscin." The quite different melanin pigment that has been noted in nerve cells is, according to Dolley,⁴ likewise not a natural constituent of any region of the nervous system, nor is it a product of normal or hypernormal functional activity. The genesis of the melanin pigment under all conditions, physiologic, morbid or senile, the Missouri investigators assert, is referable solely to depression. According to them, the histogenesis of the melanin pigment found in nerve cells is from nuclear material.

BRONCHIAL SPIROCHETOSIS

As long ago as 1905, Castellani, the student of tropical diseases, described the occurrence in the island of Ceylon of a form of bronchial infection caused by spirochetes. Since that time other observers have seen cases of bronchial spirochetosis in various parts of the world, but chiefly in the tropics. The American observers Jackson and Waters recognized the disease in the Philippines in 1908. The experiences of the recent war led to the observation that the disease was not confined to tropical countries. During the war, cases were observed in considerable number along the Adriatic coast, in Serbia, in Switzerland and in France. Recently Farah⁵ described a number of cases of the disease in Egypt. The condition is one that is usually confused with tuberculosis. It generally runs a chronic course, although it may occur in the acute form. Patients usually complain of a chronic cough which is worst on arising and toward night and is accompanied by an expectoration that is frequently bloody. In the common form of the disease, the

chronic type, the patient is usually afebrile, and no pronounced effect on the general health results. The recognition of the disease depends on the finding in the sputum of the characteristic spirochete, which was named by Castellani *Spirochaeta bronchialis*. The organism stains readily with the ordinary basic anilin dyes, but does not take Gram's stain. It generally occurs in the sputum in large numbers. Attention is called to the subject at the present time because of the return of large numbers of our citizens from service in France and other European seats of war where the disease might possibly have been contracted.

THE ATTEMPTS TO TRANSPLANT TUMORS

It has been remarked that the cancer problem, like the kingdom of heaven, is within us. An ordinary infection can be transferred from one individual to another, and the disease may often even be conveyed between individuals of different species. This is in striking contrast to what is true of most neoplasms. They do not continue to develop when introduced into another than the original host. Hence, when it was found that one or more varieties of tumors having something in common morphologically with the malignant growths of man could be transferred from animal to animal, particularly in the case of mice, the hope of finding important facts in relation to the spread of such tumors was greatly encouraged. The story of transplantation experiments in cancer research is a history of many chapters. Spurred on by the striking analogies with human experience obtained in the investigation of tumor grafts in mice, as well as by the tremendous human importance of the questions at issue, numerous investigators have turned their best energies toward transplantation studies. Despite the oft repeated experience of "negative results," the workers have persisted in what has often seemed to be a hopeless undertaking. Nothing short of the courage of mind which is a characteristic of the true man of science could have kept cancer research alive to the degree that is represented by its place in present day medical inquiry. Yet in the midst of many disappointments and of the protracted uncertainties, some positive findings and helpful information have almost always been forthcoming. Each year has witnessed the patient unearthing of some new fact that has proved to be a spur to further initiative. As an illustration of this we may cite the recent attempts of Mann¹ in the Department of Experimental Surgery at the Mayo Clinic to obtain a transplantable tumor in the higher species of animals. Heretofore all such experiments, with the exception of those dealing with the infectious sarcoma of the dog, have been failures. Mann has made a new effort to transplant tumors of the dog and cat, for the advantage of obtaining a transplantable growth in a larger species is obvious. The results obtained in the Rochester experiments were strikingly similar to those hitherto observed in autotransplantation and homotransplantation of normal tissues. The transplants of a mammary carcinoma of a dog and of a fibroma of a cat failed to

develop to any noteworthy extent on other individuals of the same species. The transplants of the fibroma which were made in the donor grew, however, and were exactly similar to the mother tumor in the cat. Mann has discovered the lesson in such experiences. The problem, he says, of developing a transplantable tumor in the higher species of animals is, it would seem, closely allied to the problem of making homotransplants of normal tissues grow. Here, again, is a fruitful field for renewed research.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Reciprocal Relations Established.—Reciprocal relations have been established between the state medical licensing boards of California and Iowa which became effective Jan. 22, 1920.

New Officers.—At the meeting of the West Side Medical Association of Kern County, held in Taft during the week of January 17, Dr. Harry N. Taylor, Maricopa, was elected president, and Dr. Allen, Taft, secretary.

Botulism Study.—A fund has been raised by the olive growers and the canning industry for an intensive study of botulism in California. The investigation will be conducted in the laboratories of the Stanford University Medical School and the George William Hooper Foundation for Medical Research of the University of California and has the cooperation of the U. S. Public Health Service and the California state board of health. A careful study will be made of the distribution of *Bacillus botulinus* in nature, of the ways in which food materials may become infected and of the steps necessary to destroy the organism when it has infected raw food materials. It is expected that the work will require at least two years.

FLORIDA

Personal.—Dr. Clarence M. Slack has been elected mayor of St. Petersburg.—Dr. John T. Bowen, Clearwater, who has been on duty with hospitals in Serbia during the world war, has received a decoration from the Serbian government.

Bequest to Health Bureau.—A citizen of Florida, who wishes to remain anonymous, has deposited with the state officer a will in which he leaves \$75,000 to carry on the fight against venereal disease. The will provides that a corporation must be formed to administer the bequest, which constitutes the major portion of the testator's fortune.

County Society Program.—The committee on scientific work of the Hillsboro County Medical Society has issued the society's program for 1920 in the form of a calendar. The meeting days of the society are red letter days to the physicians of the county. At the bottom of the page for each month appears the scientific program for the society's bimonthly meetings.

ILLINOIS

Chicago

Grant by the Fenger Memorial Association.—The Fenger Memorial Association, at the suggestion of Dr. Ludvig Hektoen, has awarded Dr. Harry B. Culver a grant to aid in the study of certain urinary infections.

Dinner to Philadelphia Neurologist.—Dr. Charles H. Frazier, Philadelphia, was given a complimentary dinner at the University Club, February 18, at which he met former service men who had been members of his classes, and afterward read a paper before the Chicago Medical Society on major trigeminal neuralgias and their treatment.

Decrease in Influenza and Pneumonia.—From more than 2,000 there was a drop to 136 cases of influenza, February 14, and pneumonia cases dropped from a maximum of 300 to

56. Eighteen deaths were reported from influenza, and twenty-three from pneumonia. On account of the improvement in the influenza situation, the ban on visiting in hospitals has been removed, and public funerals are again permitted.

Augustana Hospital Drive.—A drive of the Augustana Hospital for \$700,000 for the erection of a new building was opened, February 16, by the first of a series of ten dinners. Addresses were made by Chief Justice Harry Olson, chairman of the executive committee, Dr. William A. Evans, Mrs. C. A. Evald, and Mrs. Albert J. Ochsner. A budget was approved to apportion to the various divisions the following amounts: executive committee, \$18,245; men's division, \$22,911; women's division, \$5,454; miscellaneous, \$2,300.

Joint Meetings.—A joint meeting of the Chicago Pediatric Society and Clinic Society of the Children's Memorial Hospital was held at the hospital, February 20. Dr. John A. E. Eyster of Madison, Wis., delivered the address of the evening.—A joint meeting of the Chicago Medical Society and American Congress on Internal Medicine will be held February 25, at 8:40 p. m. Dr. A. Scott Warthin, chief of the department of pathology of the University of Michigan, Ann Arbor, will deliver an address on "The Medical Aspects of Gassing and Warfare with Particular Reference to Mustard Gas," illustrated by lantern slides.

INDIANA

Conference on Mental Hygiene.—At the Indiana Conference on Mental Hygiene held in Indianapolis, December 15, under the auspices of the Indiana Society for Mental Hygiene, President William Lowe Bryan of Indiana University, Bloomington, was elected president; Mr. Z. T. Fitzgibbon, Muncie, vice president; Mr. Paul Kirby, Indianapolis, secretary, and Mr. Edward Woollen, Indianapolis, treasurer. Medical members of the executive committee are Drs. S. E. Smith, Richmond, George S. Bliss, Fort Wayne, and Charles P. Emerson, Indianapolis.

Personal.—Dr. Columbus B. Goodwin, Kendallville, is reported to be seriously ill with pneumonia in Lakeside Hospital.—Dr. George S. Bliss, superintendent of the Indiana Home for Feeble-Minded Youth, Fort Wayne, has been appointed executive head of a similar institution operated by the United States government in Honolulu, Hawaii.—Henry C. Gemmill, director of the Fort Wayne municipal venereal clinic, has resigned to accept a position as executive officer of the seventh district of the U. S. Public Health Service with offices in Cincinnati.

LOUISIANA

Full-Time Health Work.—The Rapides Parish Police Jury has appropriated \$15,000 to be supplemented by appropriations made by Alexandria for carrying out full-time health work.

No Bubonic Plague in New Orleans.—The U. S. Public Health Service announces there have been no new cases of human plague in New Orleans since December 29. During the two months preceding, there were in all twelve cases of human plague, all of them among those employed in the large food warehouses located near the water front. The situation was promptly and effectively met by the authorities, and New Orleans is declared to be just as safe today as any other city in the country. It is just as safe to visit New Orleans as it is to visit Rome, Paris or any other large city.

MASSACHUSETTS

Tuberculosis Association Established.—The representatives of organizations in northern Massachusetts which are interested in the control of tuberculosis met, February 4, in Salem and organized the Northeastern District Tuberculosis Association, electing Israel C. Clark, Haverhill, president; Mrs. Sturges, Salem, vice president; Mrs. George G. Winchester, Gloucester, secretary, and Josiah Gifford, Salem, treasurer.

Universal Military Training Bill.—Acting on the unanimous request of the council of the Massachusetts Medical Society, the joint committee on legislation of that society and of the Massachusetts Homeopathic Medical Society, February 10, considered and unanimously endorsed the medical aspects of the bill now before Congress providing for universal military training. It was the opinion of the committee, which represents over 4,000 physicians of Massachusetts, that the detection of diseases and defects through physical examination, their relief by appropriate measures,

and the betterment of health and physique through out of door life and exercise must inevitably improve greatly the physical condition of the young men throughout the country.

MICHIGAN

Society Reorganized.—Physicians of Barry County met at Hastings, December 31, and reorganized the Barry County Medical Society, electing the following officers: president, Dr. Clarence H. Barber, Hastings; vice president, Dr. Edgar T. Morris, Nashville; secretary, Dr. Arthur W. Woodburne, Hastings.

State Officers Reelected.—At the meeting of the trustees of the Michigan State Medical Society in Detroit, December 13, Dr. Frederick C. Warnhuis, Grand Rapids, was elected secretary and editor of the official organ. Dr. David Emmett Welsh, Grand Rapids, was re-elected treasurer. It was decided that the annual meeting of the society be held in Kalamazoo, from May 25 to 27.

Personal.—Dr. Garfield Smalley, Charlotte, who has been in Central America for a number of years, is ill with tropical fever in the Charlotte Sanatorium.—Dr. Vern N. Richeson has succeeded Dr. Jeannette Brigham, resigned, as city health officer of Howell.—Dr. George K. Pratt, Flint, has been made assistant superintendent of the Oak Grove Hospital.—Dr. Lloyd C. Harvic, Saginaw, has been appointed city physician of Saginaw to succeed Dr. Leon B. Harris, deceased.—Dr. Lucius G. Fitzgerald, Port Huron, was acquitted by a jury, January 19, of the charge of performing an illegal operation.

MINNESOTA

Upper Mississippi Physicians Elect Officers.—At the annual meeting of the Upper Mississippi Medical Society held in Brainerd, January 8, the following officers were elected: president, Dr. J. A. Evert, Brainerd; vice president, Dr. F. L. Wilcox, Walker; secretary-treasurer, Dr. Irving Badeaux, Brainerd.

Overseas Medical Officers Club.—Minneapolis physicians, surgeons and dentists who served in the U. S. Army, Navy, Marine Corps or Public Health Service during the world war met, January 15, and organized a club, of which Dr. Frederick E. Haynes was elected president and Dr. Clifford E. Henry, secretary.

Deaths.—Elmer Ray Hoskins, Minneapolis; Ph.D., University of Minnesota, 1916; aged 30; Instructor in Anatomy, University and Bellevue Hospital Medical College, 1917-1918; Lieut., U. S. Sanitary Corps, 1918-1919; Associate Professor of Anatomy, University of Pittsburgh, and Assistant Professor of Anatomy, University of Minnesota, 1919; extensive contributor to the literature on the endocrine organs; died January 30, from influenza-pneumonia.—Walter W. Denny, a senior student of the University of Minnesota and an intern in St. Paul City Hospital, died January 26, from influenza.

MISSISSIPPI

Physician Sentenced.—Dr. Fletcher E. Lee, Aberdeen, is said to have been found guilty of manslaughter and sentenced to imprisonment for twenty years. Dr. Lee was charged with performing a criminal operation, as a result of which Miss Mary Miller of Aberdeen died.

Infirmity Purchased.—The locating commission of the Mississippi conference of the Methodist church has purchased the South Mississippi Infirmity, Hattiesburg, from Dr. Walter W. Crawford for \$30,000. The present building will be moved and the infirmity will continue work until new buildings to cost \$500,000 are ready for use.

NEW JERSEY

New Officers.—At the reorganization meeting of the Greenville Medical Society held in Jersey City, January 14, Dr. Samuel A. Cosgrove and Dr. Leonard B. Fauquier, both of Jersey City, were elected president and secretary-treasurer, respectively.—At the annual meeting of the Atlantic County Medical Society held in Atlantic City, January 9, Dr. Henry T. Harvey was re-elected president, Dr. Walt P. Conaway, vice president, and Dr. Edward Z. Holt, secretary-treasurer; all are residents of Atlantic City.

Personal.—Dr. Marcus A. Curry, Greystone Park, has been appointed physician in chief and medical superintendent of the Morris Plains State Hospital pending the election of a permanent superintendent to succeed Dr. Britton D. Evans,

deceased.—Dr. Philip Embury, Basking Ridge, recently sustained severe cuts and bruises when his automobile was struck and demolished by a train at a grade crossing on the Lackawanna Railroad.—Dr. Matthew K. Elmer, Bridgeton, has been elected a director of Cumberland National Bank.—Drs. David H. Oliver and Stacy M. Wilson, Bridgeton, have been elected directors of the Cumberland Trust Company.—Dr. William G. Schaufler, Lakewood, recently discharged as Colonel, Medical Corps, U. S. Army, resumed practice at Princeton, February 1.—Dr. Blase Cole, Newton, has been elected a director of the Merchants National Bank, Newton.—Dr. John R. C. Thompson, Bridgeton, has been re-elected physician of Cumberland County.—Dr. Morris R. Faulkner, Vineland, sailed from New York for South America, January 15.

NEW YORK

New Officers.—At the annual meeting of the Medical Association of Oneida County held in Utica, January 13, the following officers were elected: president, Dr. Wood Clark; vice president, Dr. John D. Jones; secretary, Dr. Daniel E. Pugh, and treasurer, Dr. Robert Sloan, all of Utica.

Welfare Legislative Program.—Social welfare and labor legislative programs were discussed at a hearing before the senate labor committee February 12. These measures include the Knight bill extending the workmen's compensation law to cover occupational diseases, a health insurance measure, and a bill regulating the working hours of women and children.

Board of Inebriety Quits.—Assemblyman Martin McCue reported to the Assembly at Albany that the New York City board of inebriety, organized in 1910 to care for persons addicted to overindulgence in intoxicants, has found no one in need of its aid and has asked to be disbanded. A bill was introduced to delegate its powers to the board of correction.

Personal.—Count Pierre de Nouy, who was here during the war working for the French Mission, arrived on the *Rochambeau*, February 11, to take charge of the new laboratories of the Rockefeller Institute in connection with Dr. Alexis Carrel's research work.—Dr. St. Clair Darden, Poughkeepsie, has been appointed superintendent of the Healthwin Hospital and has assumed the duties of his position.

New York City

Personal.—Dr. Seymour Oppenheimer has been appointed a trustee of the state institute for the study of malignant disease.—Dr. Philip F. Bernstein, Brooklyn, has been appointed diagnostician to the Brooklyn section by the New York department of health.

Sanitary Code Affecting Milk.—At a recent meeting of the board of health, section 155 of the sanitary code of the department of health was amended and the term "modified milk" was defined. Under the terms of the amendment "modified milk" means any subdivision of the classification known as "Grade A for infants and children" which has been changed by the addition of water, sugar of milk or other substance intended to render the milk suitable for infant feeding. Such milk cannot be sold without a permit from the department of health.

NORTH CAROLINA

School Clinic.—Buncombe County Medical Society has established a permanent clinic at Asheville for the treatment of schoolchildren suffering from adenoids and diseased tonsils. Arrangements have been made for operations at the Mission, Meriwether and Biltmore hospitals, the physicians donating their services, but the hospitals making graduated charges not exceeding \$12.50. The clinic will not be limited to Buncombe County, but will be open to those in western North Carolina.

Personal.—Dr. Andrew J. Warren, Raleigh, assistant state health officer, has been appointed health officer of Charlotte, succeeding Dr. C. Curtis Hudson, Charlotte, who resigned to accept a similar position in Richmond, Va.—Dr. James C. Braswell, Whitakers, was elected grand master of North Carolina masons at the meeting of the grand lodge at Raleigh.—Dr. Walter A. Newman, Wilmington, physician of New Hanover County, has been appointed field health director for Halifax County, Va.

Sanatorium Burns.—The Royal League Sanatorium, Black Mountain, with all its cottages, was destroyed by a fire originating in the power house on the night of February 15. Dr.

Isaac J. Archer, the superintendent, and the nurses and staff removed the patients without casualty to Cragmont Sanatorium, nearby. The loss is estimated at \$30,000, partially covered by insurance. This sanatorium was the first to be established by a life insurance or fraternal insurance organization for the care of its members suffering from tuberculosis.

OHIO

Starts for Prison.—Dr. William A. Charter, Marion, sentenced several weeks ago to imprisonment in the penitentiary for from one to seven years for performing an illegal operation, was taken to the penitentiary, January 21.

Peak of Influenza Epidemic.—The larger cities of the state have passed the peak of the influenza epidemic, and the mortality is presumably at its height, but it is likely that the incidence of the disease will yet be greater in smaller towns and rural districts.

Hamilton S. Biggar Prizes.—The Cleveland Medical Library Association announces a prize essay competition for two prizes, one of \$200 and one of \$100, to be designated the Hamilton S. Biggar Prizes of the Cleveland Medical Library Association. Competition is open to members of the medical profession of Cuyahoga County, senior students in Western Reserve University and interns in hospitals in Cuyahoga County. The prizes will be awarded for the best essays on some clinical or theoretical subjects of immediate clinical interest. Manuscripts must be submitted to the secretary of the association, Dr. George Edward Follansbee, on or before Oct. 1, 1920, the identity of the author being safeguarded in the usual way. The announcement of the winners of the prizes will be made at the annual meeting of the association in December.

Personal.—Dr. James W. Young, Bellefontaine, has been appointed coroner of Logan County, succeeding Dr. Horace A. Skidmore, resigned.—Dr. David E. Stephen, Lorain, was seriously injured in a collision between his automobile and an interurban car, January 14.—Dr. LeRoy Pence was elected president of the Mechanics Building and Loan Association, Lima, at its annual meeting, January 20.—Dr. Jonas E. King, Girard, has been appointed health commissioner of Trumbull County.—Dr. James J. Martin, Bucyrus, has been elected city health commissioner.—Dr. James P. Wortman, Crooksville, suffered a fracture of the leg in an automobile accident, January 20.—Dr. Robert C. Rind has been elected president of the Springfield City Hospital staff. Dr. Clarence S. Ramsey has been reelected vice president and Dr. William B. Quinn has been elected secretary.

PENNSYLVANIA

Academy Offers Use of Library.—The Pittsburgh Academy of Medicine announces that the use of its library is open to all members of the Allegheny Medical Society and that a resident librarian is on duty at the Academy building, 322 North Craig Street, from 10:30 a. m. to 2:30 p. m., daily.

New Officers.—Mercer County Medical Society held its meeting January 4 at Buhl Hospital, Sharon, preceded by a clinic and luncheon. The following officers were elected: president, Dr. Frank Bleakney, Grove City; vice presidents, Drs. Augustus M. O'Brien, Sharon, and David Ferringer, Stoneboro; secretary, Dr. Martha Edith MacBride, Sharon, and treasurer, Dr. Carl J. Mehler, Sharon.

Licenses Revoked.—Federal attorney E. Lowry Humes was notified February 8 by Dr. John M. Baldy, Philadelphia, president of the Bureau of Medical Education and Licensure, that the bureau has revoked the license of Dr. Ellsworth J. Trader of Pittsburgh, now serving a sentence in the federal prison in Atlanta, Ga., for illegal writing of prescriptions for narcotics.—Six Pittsburgh physicians have been arrested by federal agents in the last few weeks.

Philadelphia

Campaign Against Quacks.—A city-wide campaign against quack doctors was announced February 10 by assistant district attorney Charles Edwin Fox, after William J. Locker, a practitioner of drugless therapy, pleaded guilty before Judge Rogers of practicing without a license.

Provost of University Resigns.—After forty-four years of service in college work, Provost Edgar Fahs Smith of the University of Pennsylvania has tendered his resignation to the board of trustees. He announced his complete retirement from all university activities and connections, giving

up not only his office as provost which he has held since January, 1911, but also the Blanchard professorship of chemistry.

Personal.—Dr. Joseph C. Beck, Chicago, professor of rhinology, otology and laryngology of the College of Physicians and Surgeons of Illinois, read a paper on the use of radium and other nonsurgical measures in malignant disease of the head and neck, before the section on otology and laryngology of the College of Physicians, February 18.—Dr. Alonzo E. Taylor of the University of Pennsylvania sailed for Europe, February 14, to make a close study of food conditions in the "hungry sections" of the continent.—Dr. C. Lincoln Furbush, director of public health and charities, has been confined to his home with a mild attack of influenza.

VIRGINIA

Improvement of Health Administration.—The United States Public Health Service is conducting a campaign throughout the state to improve health administration in the rural districts. The work is being financed jointly by federal, state and local authorities.

Damages Against Sanatorium.—Henry Cohen, Jr., is said to have been awarded \$2,000 damages in his suit for \$10,000 which he brought against the Tucker Sanatorium, Richmond, claiming that he sustained injuries as a result of the application of hot water bags, while he was a patient in the institution in December, 1918. The attorneys for the sanatorium made a motion to set aside the verdict on the ground that the amount awarded was excessive.

WASHINGTON

Physicians Meet.—At the recent meeting of the Washington Medical Library Association held in Seattle, Dr. Samuel J. Holmes, was reelected president for the fourteenth term; Dr. J. A. Smith was elected vice president, and Dr. Charles A. Warharnik, secretary-treasurer. The number of active members of the association has increased to 177.—At the meeting of the Pierce County Medical Society held in Tacoma, February 10, the topic of the evening was an open discussion of influenza, inaugurated by Dr. Charles S. Wilson of the city health office.

Laboratory Activities.—The work of the laboratory of the Washington state board of health for January shows a large increase over previous records. The number of examinations totaled 1,318, representing an increase of 67 per cent. over the December total and of 220 per cent. over the monthly average for 1918. There has been an epidemic of diphtheria in the state, and the laboratory has been able to render efficient service in the distribution of large amounts of mediums as well as in the prompt diagnosis of cultures. The increase in the diphtheria diagnostic work is shown by the January total of 728 in contrast to the total of 915 for the entire year 1919. Virulence tests on the carrier cases have been made where requested at the expiration of the quarantine period. The Wassermann work also shows a steady increase since its introduction in 1918. The Wassermann specimens for 1918 totaled 435; for 1919 the total was 1,827, and for January, 1920, it was 278.

WISCONSIN

Hospital Items.—The new Milwaukee Maternity and General Hospital, formerly the Columbia Hospital, has been completely remodeled at a cost of more than \$10,000 and was opened for inspection, Dec. 21, 1919.—The Methodist conference is reported to be planning to buy St. Joseph's Hospital, Racine, and will erect an \$80,000 hospital building.

CANADA

Hospital News.—The old Toronto General Hospital is to be purchased by the city of Toronto and will be converted into an isolation hospital.

Medical Clinic for Kingston.—Incorporation has been granted to the Kingston Clinical Association, Limited, with a capital of \$100,000. The purpose of the association is to conduct a medical clinic which will standardize the systematic examinations. Specialists in each branch of medicine will be in charge, and all modern science equipment will be used. This will make Kingston a more important medical center, as it is the first clinic of the kind to be established in Canada. Dr. Walter T. Connell will be the director.

Public Health Notes.—Representatives of the Academy of Medicine, Toronto, and of the Ontario Medical Council,

headed by Dr. Edmund E. King, recently waited on the Ontario Government in support of the vaccination act. The physicians desire that the act be left unamended, or else strengthened by giving more power to the Ontario board of health and the medical officers of health. Every child should be vaccinated before going to school at least, and there should be subsequent vaccination if necessary. The deputation thought it would be in the interests of the community if vaccination was made compulsory.—Dr. Arthur A. Simard, Quebec, president of the provincial board of health of Quebec, reports the general health of the province as good. Close touch with the origin and spread of smallpox in Ontario has been maintained, and it has been decided not to lift the boundary quarantine against Ontario. Every precaution is also being taken against the admission of influenza into that province. This disease has been present in many points in Ontario, and although not so bad as the epidemic of 1918, a large number of deaths from influenzal pneumonia have been reported.—Toronto has had as many as thirty deaths a day from influenza, and the height of the epidemic has evidently not been reached.—The Winnipeg epidemic of encephalitis lethargica has reached sixty cases with twenty-three deaths, an unduly high mortality rate of 38 per cent. In eighteen cases the brain was examined and showed marked congestion, perivascular infiltration with lymphocytes and plasma cells, and occasionally hemorrhage. Degeneration of the nerve cells was variable, the changes being most marked in the midbrain. Marked lesions were also found in the kidneys. A remarkable epidemic of hiccup occurred in Winnipeg at the same time.

FOREIGN

Fuchs in Spain.—On the invitation of the Junta de Ampliación de Estudios (Postgraduate Studies' Board), Dr. E. Fuchs, professor of ophthalmology at the University of Vienna, will deliver a course of lectures at Madrid on the pathology of eye diseases. In addition, his lectures will be supplemented by explanations by Dr. Cajal.

Deaths in the Profession Abroad.—Dr. H. Müller, professor of internal medicine at the University of Zurich until 1918, aged 71. Percussion and auscultation were his hobbies, he used to say, and he used them in perfecting the diagnosis of heart disease so that under his teachings congenital heart disease is detected earlier and in larger proportions in Switzerland, it is said, than elsewhere.—Dr. Julio Robert, physician to the French embassy at Madrid and to the French hospital, director of the first infant consultation station at Madrid.

Prize for Research on Nerves.—The *Nederlandsch Tijdschrift* publishes a notice from the University of Leyden to the effect that the Bachien prize of at least 500 florins, with a parchment certificate, will be awarded for the best work on the recording of the electric phenomena in the living body of certain nerves that have not already been thus studied. The nerves that have been already investigated are the phrenic, the vagus of the lung and the depressor nerves. It is stated that competition is open to all, and the competing articles describing the research can be in Dutch, French, English or German. They must be in the hands of the secretary, H. Krabbe, Witte Singel 28, Leyden, Netherlands, before March 1, 1921.

LATIN AMERICA

Influenza in Havana.—On account of the prevalence of influenza, the health officer of Havana, Dr. López del Valle, has put in force several measures to combat the spread of the disease. Among the measures adopted are the forbidding of all mask balls and children's dances, the placarding of houses where cases occur and the restricting of public funerals.

Tribute to Dr. Vieira de Carvalho.—The *Annaes Paulistas de Medicina e Cirurgia* of São Paulo, Brazil, describes the ceremonies which have been organized by the Santa Casa in honor of the completion of thirty years as director of that public hospital by Dr. Arnaldo Vieira de Carvalho, professor of forensic medicine in the law school there and one of the founders and organizers of the Faculdade de Medicina e Cirurgia. The faculty will present him with a bronze bust at the public meeting planned at the Theatro Municipal, where a gold medal and a parchment describing his record as physician, administrator and citizen will also be presented. Representatives from scientific institutions in other states have announced their intention to attend as well as numbers outside of scientific circles.

GENERAL

Personal.—Drs. William J. Mayo, Rochester, Minn., and Franklin H. Martin, Chicago, who have been touring South America in the interests of a possible Pan-American College of Surgeons, started for home from Santiago, Chile, February 14. In the course of their tour they have visited Buenos Aires, Montevideo and Valparaíso, Chile.

Delegates to World Red Cross Meeting.—The American Red Cross has announced the appointment of the following delegates to the first meeting of the general council of the League of Red Cross Societies at Geneva, Switzerland: Willoughby G. Walling, Chicago; Otis H. Cutler, New York; Mrs. William K. Draper, New York; Samuel Mather, Cleveland, and Eliot Wadsworth, Boston. Mr. Henry P. Davidson, chairman of the board of governors of the league, will accompany the delegation. The council will open in Geneva, March 2, and will continue in session one week. Twenty-four powers have been invited to send delegates from their national Red Cross societies.

Bill to Suppress Bubonic Plague.—To continue the work for suppression and control of bubonic plague in New Orleans, Senator Ransdell of Louisiana has presented to the Senate an amendment to the deficiency bill, appropriating \$250,000 for the immediate use of the Public Health Service. This is in accordance with the recent request of the Public Health Service, which has no available funds at the present time to suppress the bubonic plague and similar epidemic diseases. The Clearing House Association of New Orleans is cooperating with the Public Health Service and has agreed to lend the New Orleans Dock Board \$500,000 to finance the operations of local authorities in rat-proofing operations on the docks.

Air Service Medical Association.—Medical officers formerly or at present connected with the air service of the Army have organized the Air Service Medical Association of the United States and have elected the following officers: president, Dr. John A. McReynolds, Dallas, Texas; vice presidents, Col. Theodore C. Lyster, New York City; Col. Eugene R. Lewis, Dubuque, Iowa; Col. Isaac H. Jones, Philadelphia; Col. William H. Wilmer, Washington, D. C., and Col. Albert E. Truby, Washington, D. C.; secretary, Major Vernon K. Earthman, Dallas, Texas, and treasurer, Major Robert S. McCombs, Philadelphia. The next annual meeting of the association will be held in the St. Charles Hotel, New Orleans, April 26.

Resolution Regarding Dr. Osler.—At the meeting of the executive committee of the Federation of American Societies for Experimental Biology in Cincinnati, Dec. 30, 1919, a minute was drafted, stating:

In the death of Dr. Osler, the medical profession has suffered an immeasurable loss. Belonging to no cult, or age, or clime, . . . he was master of the art of medicine in its purest form. . . . As a teacher, he was again master, painting with broad strokes pictures of disease never to be forgotten by the student. An investigator and an inspirer of investigation, a worthy counsellor of brother physicians, a deliver in the history of medicine, and an ornament to its letters; and withal so human and of such rare personal charm as to be beloved of all who came in contact with him. Such was the man we mourn. We grieve not only at the loss of leader and friend, but also that death overtook him in the very shadow of the great conflict which brought him so great personal loss and sorrow and robbed him of the mellow years which were so fully his due.

Incidence of Influenza.—The U. S. Public Health Service reports the incidence of influenza for the month of January as being excessive. In thirty-one states which have sent reports, there were over 120,000 cases. The mildness of the disease is generally commented on, and it is believed that many physicians are not reporting mild cases of influenza. Mortality reports from large cities indicate that from May, 1919, to January, 1920, the death rates from influenza and pneumonia were "quite generally below the general average." With the week ending January 17, which marked the beginning of the influenza epidemic in Chicago, the death rate from influenza and pneumonia in Chicago increased slightly, but is still not in excess of the average for the season. Similar significant increases have taken place in New York City, Washington, D. C.; Milwaukee, Kansas City, Mo., St. Louis, Cleveland, San Francisco, Albany, N. Y., Atlanta, Ga., Baltimore, Cambridge Mass., Columbus, Ohio, Dayton, Ohio, Indianapolis, Jersey City, N. J., Louisville, Ky., Minneapolis, Newark, N. J., New Haven, Conn., Philadelphia, Pittsburgh, Richmond, Va., St. Paul, Syracuse, N. Y., and Toledo, Ohio.

Regulations for Prescribing Liquors

A circular issued by the Commissioner of Internal Revenue gives explicit directions regarding Form 1403, prescription blanks for practicing physicians who have secured permits to prescribe liquor. As stated in the abstract of Internal Revenue Regulations 60 (THE JOURNAL, Jan. 31, 1920, p. 342), it is first necessary for practicing physicians to secure a permit to prescribe. Application for such a permit must be made on Form 1404, in triplicate, sworn to before a notary public. These blanks can be secured from the federal prohibition director of the state or from the collector of internal revenue of the district in which the physician making application is located. Permits will be issued only to physicians legally qualified to practice under the laws of the state. The three copies when filled out are returned to the federal prohibition director. After receiving a permit to prescribe, the physician is then supplied with Form 1403 on which prescriptions for alcohol and alcoholic liquors must be made out. These prescription blanks are furnished in books of 100 blanks each. A sample blank is reproduced in the adjoining column. The books are serially numbered, and each prescription blank in each book is also serially numbered, with stubs attached. Books must be returned to the director when the prescription blanks have all been used, or sooner if ordered by the director or the Commissioner of Internal Revenue. All unused, mutilated or defaced blanks must be returned with the books.

The state directors and the district collectors of internal revenue by whom these prescription books will be issued are directed to keep a record of the books issued to each physician. Prescription books can be secured by physicians only after they have made application in triplicate on Form 1404 for a permit to prescribe and after the permit has been issued on Form 1405. No bond is required for such a permit. A register is also issued to each physician in which must be recorded all prescriptions written for alcohol or liquors.

Instructions regarding the administration of liquors in accordance with the regulations are explicit. They read as follows:

"Regulations No. 60 provide that distilled spirits, wines and alcoholic medicinal preparations may be administered by physicians to their patients for medicinal purposes in cases where the use of such liquor is believed necessary to afford relief of some known ailment, and delay in procuring the same through a retail pharmacist upon a prescription might result in loss of life, aggravation of the ailment, or intense suffering. Physicians may make application on Form 1404 for permit for this purpose, and if approved a permit will be issued by the commissioner to the physician to use the liquor in the course of his practice, and he may obtain as much as six (6) quarts of liquor during any calendar year, to be administered as stated above, but he may not sell or furnish the same to such persons or to any other persons." Permits to prescribe may be issued by state prohibition directors, but permits to physicians to use liquor for administration to their patients must be issued by the Federal Prohibition Commissioner.

"Physicians are not permitted to write prescriptions for liquor for their own use, and the law provides that not more than a pint of spirituous liquor to be taken internally shall be prescribed for use by the same person within any period of ten days, and no prescription shall be filled more than once."

Druggists qualified to sell medicinal liquors are notified that all prescriptions for medicinal liquor must be on Form 1403 except that in any case where a physician holding a permit to prescribe liquor is not in possession of such a form due to any justifiable reason and where delay in procuring this form might result in loss of life, aggravation of the illness or intense suffering, he may prescribe intoxicating liquor on a form other than Form 1403 provided such prescription contains all of the information called for on Form 1403 and a record of the prescription is made.

Disease Conditions in the Army

For the week ending February 6, it is reported that influenza continues at many of the large camps and stations, principally among the eastern and southern states. The number of new cases of pneumonia for that week was double the number reported for the previous week. Admission and noneffective rates showed a slight decline. There was a marked decline in the number of new cases of influenza, measles and pneumonia occurring among the American forces in Germany. The incidence of pneumonia in the camps in the United States is about one tenth of that accompanying influenza at the height of the 1918 epidemic. The mortality percentage was also much lower.

The Attitude of French Societies of Learning Toward German Savants

Notwithstanding the fact that the treaty of peace has gone into effect, there are as yet no indications that relations between French and German men of science are about to be resumed. It will be recalled that it was the attitude of the ninety-three signatories of the all too famous manifesto of German intellectuals that induced our academies to break with the German savants. Before the war, Germany had, to a certain extent, reserved to herself the monopoly of treatises on natural science, and France saw fit to buy and use them, but does not propose to do so longer. The Sociétés françaises de sciences naturelles have recently formed a federation for the purpose of combating German enterprise in this field. The Sociétés françaises de chimie have also formed a federation with the same object in view.

It is interesting to note that the attitude of German men of learning during the Franco-Prussian War of 1870-1871 was far from being correct, just as was the case in the War of 1914-1918. Dr. Léon Cheinisse has published some extracts from the correspondence of the celebrated German jurist Rudolf von Ihering, who, under date of Aug. 23, 1870, wrote:

"Happy is the man who is permitted to play a part in this towering flight of our people! . . . Never before in the history of any people has there been such a glorious epoch. . . . It is like the German tale of Cinderella, who was suddenly raised to the rank of princess. Thanks be to these dogs of Frenchmen for having, up to the present time, treated our people as Cinderella was treated. The application of the story has thus been brought home to their conscience, and the blows have fallen on their own shoulders. The humiliation and weakness of France must ever remind Frenchmen of our cause for gratitude. . . ."

It may perhaps be assumed that the arrogance of the German mentality, which still persists in spite of everything, and of which THE JOURNAL recently cited a typical example (THE JOURNAL, Dec. 20, 1919, p. 1889), will be no slight obstacle to the resumption of normal relations with the scientists and scholars of the empires of "Mitteleuropa."

Child Welfare in the United States

Dr. P. F. Armand-Delille, who was sent last year on a mission to the United States, recently reported to the Académie des sciences morales et politiques his impressions of the child welfare movement in that country. In his report he brought out the fact that in the United States the care of children's health has been thoroughly organized, and commended the system of visiting nurses; the consultations held in the homes with mothers and prospective mothers, the

teaching of hygienic rules, and the care of the child who may be ill. He also emphasized the value of the American federation of charity organizations, which made possible a better utilization of charity funds from public and private sources. He found that the heartiest cooperation prevailed, which resulted in the greatest benefit to public health in general.

This visit of Dr. Armand-Delille furnishes an additional example of the salutary influence that the United States is destined to exert on the development of public hygiene in France. In a previous letter (THE JOURNAL, Jan. 31, 1920, p. 338) I mentioned other evidences of such influence.

Antipyrin and Anaphylaxis

Dr. Fernand Widal, professor of clinical medicine at the Faculté de médecine de Paris, in collaboration with Dr. Pasteur Vallery-Radot, has made an interesting report to the Académie des Sciences on an anaphylactic state produced by a nonalbuminoid substance—antipyrin. A woman, aged 24, had formed the habit of taking antipyrin every month for the relief of headache. During a period of nine years no untoward effects were produced, but at the end of this period anaphylaxis appeared, together with an intense pruritus at the level of the chin and lips, which became red, swollen and painful. This anaphylactic state was so persistent that it continued for seven years after the patient had completely abstained from the drug. Widal and Pasteur Vallery-Radot have been investigating for the purpose of discovering how small a dose must be to exclude all possibility of accident, and they find that it lies between 0.0001 and 0.0002 gm. Patients to whom these minute doses are administered for a period of two months are desensitized completely and definitively and they can take antipyrin tablets without feeling the slightest discomfort.

Widal remarked that analogous conditions doubtless existed for a number of substances that are ingested and inhaled. He mentioned particularly the case of a merchant who, after having sold mutton for more than thirty-seven years, was no longer able to handle mutton without having an attack of asthma. Our temperamental nature may, then, be continually modified, by the process of sensitization and desensitization; by anaphylactic shocks that take place totally unknown to us. It seems that asthma, migraine, and certain other morbid states with which man is affected during certain periods of life, are obedient to the laws of anaphylaxis.

Medical Relations with Poland

At the instance of Professor Letulle, the first meeting of the Comité médical franco-polonais was held recently at the Faculté de médecine de Paris. This committee, which was presided over by Professor Roger, dean of the Faculté de médecine, counts among its members a number of physicians of Polish extraction; for example, Dr. Babinski, hospital physician of Paris; Dr. Danysz of the Institut Pasteur, and Dr. Ockinzyc, hospital surgeon of Paris. A similar committee has been appointed in Warsaw, and the hope is expressed that before long, by means of journeys in the interest of science and by courses of lectures, scientific relations between Poland and France may be restored.

Vehicles for the Use of Cripples

Marshal Pétain has taken steps to promote an exhibit of vehicles for the use of cripples, which will be held in the Grand-Palais.

LONDON

Jan. 24, 1920.

A New Surgical Organization

The Association of Surgeons of Great Britain and Ireland, at the inaugural meeting of which Sir Rickman J. Godlee presided, owes its inception to the suggestion of Sir Berkeley Moynihan in 1914. England was then almost alone in having no representative society for the adequate discussion of surgical topics. At a meeting held at the Royal College of Surgeons, May 26, 1914, a committee was appointed to draw up rules and to circularize the members of the surgical staffs of hospitals connected with teaching schools. The war interrupted the project, and after more than five years, organization of the association has been effected. Two main principles have been kept in view: First, the active membership of the association will be limited both in respect to members and to age. Second, the discussions will be free, in every meaning of the word and the expression of thought will be untrammelled by the dread that what might be said confidentially to a friend will be repeated in a garbled form from the

housetops. No reports will be sent to the journals or newspapers, but the fellows will be at liberty to publish their communications when and where they choose, appropriately in the *British Journal of Surgery*. Experience of other countries shows the advantage of holding meetings at different centers, but it is proposed that at least every third meeting shall be held in London. It is hoped that stagnation in the directorate will be avoided by the annual change of president and one third of the ordinary members of council, and continuity will be secured by the more or less permanent tenure of office by the honorary treasurer and secretary.

Miners' Nystagmus

At a meeting of the North Staffordshire Institute of Mining Engineers, Dr. T. L. Llewellyn, medical officer to the collieries of North Staffordshire, declared that deficiency of illumination is the dominating factor in the causation of miners' nystagmus, and, in his opinion, so important that all other factors become insignificant. In the prevention of the disease three main considerations must be taken into account: 1. Nystagmus is a disease of gradual onset; the average number of years of underground life before failure of sight is twenty-five. 2. The illumination in open-light pits is five times that in safety-light pits. 3. Cases of nystagmus, although uncommon, do occur in open-light pits.

The True Nature of Multiple Exostoses

At a meeting of the Medical Society of London, Prof. Arthur Keith read an important paper on the true nature of multiple exostoses. From the study of the roentgen-ray records of four cases of multiple exostoses he had come to the conclusion that the disease should be removed from the category of tumors and placed among the disorders of growth under the name suggested by Morley Roberts—diaphysal aclasis. The exostoses which attracted the attention of the clinician are merely secondary results which mask one of the most remarkable disorders of growth. In one case the patient was a private, aged 20, in a labor battalion who was diagnosed in the Third Canadian General Hospital as suffering from multiple exostoses. The lower ends of the femurs and the upper and lower ends of the shafts of the tibias represented an arrest of bone development, which was to be anticipated if John Hunter's teaching on the growth of bones was correct. Hunter was the first to perceive that the shaft of the long bones grew by a double process: In the first process new bone is laid at the extremities of the shaft in the diaphysal lines; in the second, which Hunter named the "modeling process" the cancellous bone laid down is rebuilt, trimmed and gradually converted into an architectural part of the shaft. In diaphysal aclasis the modeling process is arrested; hence between the properly formed part of the shaft and the epiphysal end there is interposed an irregular cylinder of imperfectly modeled bone, on the surface of which there are several outgrowths. Further investigation of the case showed that the diaphysal ends of all the bones of the body manifested a similar disturbance of growth, the disturbance being greatest at the lines where growth is most vigorous and prolonged. A clue to the true nature of the disease is given by noticing its incidence on the skeleton. Bones formed in membrane or in cartilage are not affected. It is only where the two processes—membrane formation and cartilage formation—come into juxtaposition that this disorder of growth occurred. Hence it is most marked at the growing ends of diaphyses of long bones, especially those where growth is greatest. The proximal end of the humerus and the distal ends of the radius and ulna show a much greater disturbance of growth than the shafts which end at the elbow joint. In the lower extremity, growth is greatest at the diaphysal ends directed toward the knee, and there the disturbance is greatest; but as there is also considerable growth at the proximal end of the shaft of the femur and at the distal ends of the tibia and fibula, these parts also exhibit ample evidence of the disease. At these sites two different kinds of bone formation are in progress. As bone is laid down within the growth disk (epiphysal line) in cartilage a covering of fibroblastic bone is being deposited by the growing margin of the overlying periosteum. We have so concentrated our attention on the process of ossification, which takes place in the cartilaginous growth disk, that we have left out of sight the equally important processes which go in the ferrule of periosteum which surrounds the growth disk. Consequently we are not prepared to encounter a dislocation in the harmony with which these two processes ought to proceed. In achondroplasia the arrest of the growth is a partial cessation of the growth process which goes on within the cartilaginous disk. In

diaphysal aclasis the arrest lies in the growing edge of the periosteal ferrule. Hence large areas of cartilage-formed bone are left exposed. This arrest of periosteal formation is only temporary. The modeling process which is attended by the deposition of periosteal bone goes on for years after all growth in length has ceased. This conception of multiple exostoses is not new. Hunter emphasized its constitutional nature. Paget recognized it as an ossific diathesis due to some morbid condition of the blood. Several German writers have recognized it as a disturbance of growth.

Nephritis and Military Service

The discovery during the war of "trench nephritis" has led the Medical Research Committee to institute an inquiry into the condition of the soldier's kidney. The main work devolved on Capt. Hugh MacLean, whose report involves an examination under war conditions of 50,000 men. He began by attempting to find out whether there was a tendency during training for symptoms of kidney trouble to develop in ordinary recruits. He found that only 2 per cent. gave any indication of kidney mischief. He concluded that no injurious effects are produced on the kidney by any of the conditions associated with training for active service. The soldier during training does not appear to be more liable to deleterious kidney effects than is the civilian in ordinary life. No relation between albuminuria and occupation was found. Long service exercised no ill effects on the incidence. It was thus evident that trench nephritis was not a condition carried over from civil life. Further work confirmed this view. Conditions such as length of service, previous illness, age and occupation seemed to play no part in its etiology. Many of the cases developed in men who had been in the front area only a short time. Other factors—diet, infection, water supply and so on—were excluded. By elimination, the conclusion was reached that the most probable cause of trench nephritis is infection by means of body vermin, probably lice. The mortality from the disease was low in the first instance; but relapses occurred, and some of the cases became chronic. They were found to fall into the same groups as ordinary Bright's disease—interstitial and parenchymatous.

Piteous State of Wounded Serbians—Serbian Surgeons to Be Trained in England

Sir John Lynn-Thomas, the orthopedic surgeon of Cardiff, who returned recently from Serbia, paints a gloomy picture of the state of the wounded and disabled in that country. The land is filled with cripples, many of whom could be cured or improved by modern orthopedic methods. The contrast between what has been accomplished in England by Sir Robert Jones and his co-workers and the state of the broken soldiers of our ally is piteous. These men are without the simplest appliances, and the country lacks surgeons with the requisite knowledge of the new methods. It is felt by the Serbian Red Cross Society in Great Britain that the proper method to help these soldiers is to invite Serbian surgeons to come to this country to study British orthopedics under our most distinguished men. This invitation has been sent, and a favorable reply is expected.

RIO DE JANEIRO

Jan. 10, 1920.

Bubonic Plague

In the shipments of alfalfa and wheat imported from Buenos Aires, rats infected with bubonic plague were discovered. Shortly after, several cases of plague occurred among the men working on the docks at Rio de Janeiro. There were ten cases reported, but no deaths.

Institute of Medical Research

Dr. Rocha Lima, formerly of the Instituto de Manguinhos, Rio de Janeiro, and lately professor at the university and chief of the section on pathologic anatomy in the institute of tropical diseases in Hamburg, has been offered the position of director for the Butantan Institute for Medical Research. He is expected in Rio at the end of January, when he will give a definite answer.

Medical School Changes

Dr. Alfredo de Andrade has been promoted to professor of analytic chemistry, and Dr. Adelino Pinto has been appointed in his place.

Federal Department of Public Health.

The law creating the federal department of public health was approved by President Pessoa, January 20. As men-

tioned in a former letter, the creation of a ministry of public health did not meet the approval of congress. There will be three boards under the supervision of the department, namely, a board of health for Rio de Janeiro, a board of rural sanitation, and a board of maritime and fluvial prophylaxis. Besides these, there will be sections dealing with sanitary statistics; sanitary engineering; the supervision of drains; the prevention of leprosy and venereal diseases; the supervision of the practice of medicine, pharmacy, dentistry and obstetrics, and hospitals for contagious diseases and child welfare. The federal government takes charge of meat and food inspection and of all the functions of the municipal health service.

Under the law, a supreme council of hygiene and public health is appointed. The following officials are members of the board: the president of the department of health, the directors of the above mentioned divisions, the professor of sanitary engineering in the polytechnic school, the surgeon-general of the army, the chief of the navy medical corps, and the government legal adviser. The exclusion from this board of the professor of hygiene and of the dean of the medical school, as well as the president of the Academia de Medicina, was not favorably received in medical circles.

The cost of rural prophylaxis and sanitation of the interior will be met by a special tax on alcoholic drinks, by the income from the different laboratories pertaining to the department of the interior, 15 per cent. of the revenue of gambling houses, clubs and casinos at health resorts, and a stamp tax of from 20 to 200 reis on all tubes of serums, vaccines, opotherapeutic products and on all drugs either foreign or domestic. Public opinion is not in favor of licensed gambling.

Infectious Disease in Brazil

In an address to medical graduates, Dr. Afranio Peixoto protested vehemently against the erroneous impression that Brazil is one great hospital. Many prominent physicians seem intent to convince the public that there are scarcely any healthy persons in the population of 25,000,000, and that those who are lucky enough to escape from malaria or hookworm disease are infected with the Brazilian trypanosomiasis. Just because Chagas saw some cases of the disease which bears his name in Lassance (state of Minas), one physician has gone to the extreme of asserting that 15 per cent. of the population is infected with *Trypanosoma cruzi*.

Election of Officers

At a meeting of the Sociedade de Medicina e Cirurgia, December 30, the following officers were chosen: president, Prof. Fernando Magalhães; vice presidents, Dr. Julio Monteiro and Dr. Plinio Marques; secretary-general, Dr. Leonel Gonzaga; secretaries, Dr. Edilberto Campos, Dr. Arnaldo de Moraes and Dr. Theophilo de Almeida; speaker, Dr. Octavio Ayres; librarian, Dr. Catao; custodian of the museum, Dr. Del Vecchio, and editor of the annals, Dr. Guarany Goulart.

Marriages

EUSTACE HAROLD PRESCOTT, Lieut., M. C., U. S. Navy, Edgefield, S. C., to Miss Alpha Hammond of Edgefield County, S. C., at Augusta, Ga., February 1.

BENJAMIN FRANKLIN DAVIS, Chicago, to Miss Marie Lucile Brickson of Stoughton, Wis., February 7.

JAMES SYLVESTER ANTLE, Utica, Ill., to Miss Margaret Walter of LaSalle, Ill., in Chicago, January 17.

ALBERT WARD McCALLY, Dayton, Ohio, to Miss Edna Fiegenbaum of Edwardsville, Ill., December 25.

CHARLES LYNDON OUTLAND, Tarboro, N. C., to Miss Alice Louise Sadler of Richmond, Va., January 21.

KINTON DORION, Lawrence, Mass., to Miss Angelina Tessier of New Bedford, Mass., January 26.

J. J. FITZGERALD, Granite City, Ill., to Miss Georgia Coudy of Louisville, Ky., December 3.

PAUL WESLEY BEST, Atlanta, Ga., to Miss Louise Cotton of Waco, Texas, January 21.

CHARLES A. WADE to Miss Florence Marie McGeehan, both of Chicago, February 8.

LYMAN OVERSHINER, Indianapolis, to Miss Ella Ingles, in Indianapolis, December 13.

Deaths

Correction.—The obituary notice of Dr. William J. Humphrey, Union City, Pa., which appeared in THE JOURNAL of Dec. 27, 1919, was incorrect. Dr. Humphrey informs us that he is alive and well. The source of information was a notice which appeared in an Eastern medical journal.

Melvin George Overlock, Worcester, Mass.; Baltimore Medical College, 1896; aged 54; a member of the Massachusetts Medical Society; a specialist in tuberculosis, and instrumental in securing legislation requiring the maintenance of tuberculosis hospitals in cities and towns of Massachusetts; state medical health inspector; a trustee of the Worcester City Hospital since 1900; died in that institution, January 30, from diabetes.

Oliver Thompson Hyde ☉ Albuquerque, N. M.; College of Physicians and Surgeons in the City of New York, 1901; aged 44; a specialist in tuberculosis, and for six years director of the St. Joseph Sanatorium, Albuquerque; for several years resident director of a sanatorium in Silver City, N. M.; formerly a member of the faculty of Drake University, Des Moines, Iowa; died, February 2, from tuberculosis.

Royal A. Gove, Tacoma, Wash.; College of Physicians and Surgeons, Keokuk, Iowa, 1878; aged 63; a member of the Washington State Medical Association; for twelve years secretary of the Pierce County Medical Association; for six years a member of the State Board of Medical Examiners, and for two years its chairman; from 1892 to 1896 a member of the city council; died, January 21.

Francis Pollock Ball ☉ Lock Haven, Pa.; University of Pennsylvania, Philadelphia, 1877; aged 63; once president of the Medical Society of the State of Pennsylvania; who was one of the guests of honor at a banquet given by the Clinton County Medical Society in 1918; chief surgeon of the Lock Haven Hospital; died in Williamsport, Pa., January 31, from angina pectoris.

William Henry Cook, Coffeen, Ill.; Washington University, St. Louis, 1867; aged 85; a member of the Illinois State Medical Society; a charter member of the District Medical Society and for two years its secretary; one of the organizers of the Montgomery County Medical Society, and at one time its president; died, January 28, from senile debility.

James H. Shorter ☉ Macon, Ga.; Long Island College Hospital, Brooklyn, 1875; aged 69; oculist and aurist to the Macon Hospital and to the Southern Railway; a member of the American Academy of Ophthalmology and Oto-Laryngology, and of the American Laryngological, Rhinological and Otological Society; died, February 2.

Francis Torrens Stewart ☉ Philadelphia; Jefferson Medical College, 1896; aged 45; professor of clinical surgery in his alma mater; since 1910 surgeon to the Jefferson and Germantown hospitals, and for twenty-five years a member of the surgical staff of the Pennsylvania Hospital; author of a manual on surgery; died, February 4, from uremia.

Claude Dewes Hamilton, Canton, Ohio; College of Physicians and Surgeons, Baltimore, 1913; aged 31; a member of the Ohio State Medical Association; who served as captain, M. R. C., U. S. Army, and was discharged, April 4, 1919; died in Phoenix, Ariz., January 30, from pulmonary tuberculosis.

Fred Grey Benton ☉ Major, M. C., U. S. Army; University of Syracuse, N. Y., 1912; aged 33; who entered the Medical Reserve Corps, June 29, 1916; was graduated from the Army Medical School, June 10, 1917, and promoted to captain and major, Aug 3, 1918; died at Fort Anrora, January 18.

Lyle Gunn Thornton ☉ Lieut., M. C., U. S. Army, Westpoint, Texas; Chattanooga (Tenn.) Medical College, 1897; aged 45; physician of Colorado County, Texas, and assistant city physician of Westpoint; died at Fort Sam Houston, San Antonio, Texas, January 15, from valvular heart disease.

Ridgeley Brown Warfield ☉ Baltimore; University of Maryland, Baltimore, 1884; aged 56; professor of surgery in his alma mater; formerly associate professor of anatomy in Baltimore Medical College; chief surgeon of the Maryland General Hospital; died, February 4, from heart disease.

Harry A. Medernach, Portland, Ore.; Chicago College of Medicine and Surgery, 1904; aged 42; who served during the war as a secretary of the Knights of Columbus, at Camps Lewis, Ballard, and Vancouver, Wash., died, January 28.

☉ Indicates "Fellow" of the American Medical Association.

Richard Cooke Harley, Newark, N. J.; George Washington University Medical School, Washington, D. C., 1904; aged 41; a member of the Medical and Chirurgical Faculty of Maryland; formerly health officer of Prince Georges County, Md.; died, February 4, from pneumonia.

Henry Brown Conrad, South Bend, Ind.; Johns Hopkins University, Baltimore, 1916; aged 29; who resigned from an internship in Johns Hopkins Hospital to enter the Navy, and was relieved from active duty with the U. S. N. R. F., Nov. 26, 1919; died, January 29, from pneumonia.

Crandall Loughery, Montreal; McGill University, Montreal, 1918; aged 28; who served with the Canadian Army Medical Corps in France in 1918 and 1919; a member of the staff of the Montreal General Hospital; died in that institution, Oct. 25, 1919, from bronchopneumonia.

Peter Winston, Farmville, Va.; University of the City of New York, 1860; aged 83; a member of the Medical Society of Virginia; surgeon in the Confederate Service during the Civil War; for fifteen years physician to the State Normal School; died, about January 30.

Sally Robinson Creighton Best, New York City; Cornell University, New York City, 1899; aged 50; a member of the executive committee of the American Woman's Hospitals, and active during the war in the censorship of drugs for the government; died, February 6.

Frank C. Hershey, Carmel, Ind.; Medical College of Indiana, Indianapolis, 1894; aged 53; a member of the Indiana State Medical Association; health officer of Hamilton County; died, February 4, from septicemia, due to a slight scratch of the hand.

John W. Starr, Pocahontas, Iowa (license, Iowa, examination, 1889); aged 61; a member of the Iowa State Medical Society; once secretary and treasurer of the Pocahontas County Medical Society, and city physician; died, January 17, from angina pectoris.

William Francis Gillim, Chicago; University of Louisville, Ky., 1871; aged 73; a member of the Kentucky State Medical Association; for many years a practitioner of Owensboro; while returning to his old home in Owensboro, February 4, died at Evansville, Ind.

Boyer Smith Kofford, Youngstown, Ohio; University of Buffalo, N. Y., 1917; aged 25; lieutenant, M. C., U. S. Army, with service overseas and discharged, Feb. 15, 1919; a member of the staff of the Youngstown Hospital; died, January 27, from pneumonia.

Frank Boutelle Fuller * Pawtucket, R. I.; Harvard University Medical School, 1878; aged 66; acting superintendent of health of Pawtucket; for several years medical examiner (coroner) for the Pawtucket district; died, January 23, from heart disease.

Beauregard Ross Merritt, Fancy Farm, Ky.; Marion-Sims Medical College, St. Louis, 1891; aged 50; a member of the Kentucky State Medical Association; one of the owners of the Dawson Springs Sanitarium; died in that institution, January 24.

Marvin William Duckwall, Dayton, Ohio; Miami Medical College, Cincinnati, 1902; aged 40; a member of the Ohio State Medical Association; for many years a member of the board of St. Elizabeth's Hospital; died, February 1, from tuberculosis.

Milton Harlan Cloud * Masontown, Pa.; Miami Medical College, Cincinnati, 1886; aged 62; a director and for several years vice president of the Masontown Bank; vice president of the Masontown Glass Company; died, January 27, from meningitis.

Robert Bruce Duncan, Petaluma, Calif.; Missouri Medical College, St. Louis, 1873; aged 73; coroner and public administrator of Colusa County in 1888; twice health officer of Petaluma; died in the Petaluma Hospital, January 3.

Joseph P. Ralston, Jr. * Houston, Texas; University of Texas, Galveston, 1896; aged 49; was crushed between the elevator and the wall of the elevator shaft in the Kress Building, Houston, February 2, and instantly killed.

Raymond Jack Hauser * Lieut., M. C., U. S. Army, Danville, Pa.; University of Pennsylvania, Philadelphia, 1910; aged 33; on duty at Camp Grant, Rockford, Ill., died, January 18, from pneumonia complicating influenza.

Alexander John Macaulay, Brockville, Ont.; Trinity Medical College, Toronto, 1888; aged 55; medical officer of health of Brockville; president of the Ontario Medical Health Officers' Association in 1906; died, October 27.

William Alexander Molson, Montreal; McGill University, Montreal, 1874; M.R.C.S. (Eng.), 1875; coeditor of the *Canada Medical and Surgical Journal* from 1879 to 1882; died, January 5, from cardiorenal disease.

Richard F. Boonstra, Detroit; University of Michigan, Ann Arbor, 1913; aged 31; lieutenant, M. C., U. S. Army; on duty with the air service and discharged, March 4, 1919; died, January 30, from pneumonia.

Rollin Alanson Curtiss, Stratford, Conn.; University of the City of New York, 1893; aged 53; a member of the Connecticut State Medical Society; died, January 28, from cerebral hemorrhage.

Logan M. Thompson, Atlanta, Mo.; College of Physicians and Surgeons, Keokuk, Iowa, 1880; aged 61; a member of the Missouri State Medical Association; died in Macon, Mo., January 19.

Charles Henry Waters, Dawsonville, Md.; University of Maryland, Baltimore, 1871; aged 70; for many years pastor of the Trinity Baptist Church, near Dawsonville, Md.; died, January 26.

Morgan Shell Evans, New Orleans; Tulane University, New Orleans, 1917; aged 26; an intern in the State Charity Hospital, Natchez, Miss.; died, January 21, from tubercular meningitis.

William Harrison Wilson * Johnson City, N. Y.; Bellevue Hospital Medical College, 1888; aged 56; physician and surgeon to the Binghamton City Hospital; died, about January 23.

J. Sion Smith, Fort Wayne, Ind.; Fort Wayne (Ind.) College of Medicine, 1891; aged 71; superintendent of several branches of the Bass foundries, Fort Wayne; died, January 24.

Jesus Monagas, Mayaguez, P. R.; University of Barcelona, Spain, 1883; aged 58; a member of the Porto Rico medical Association; died, January 27, from cirrhosis of the liver.

Edwin T. Myers, Netawaka, Kan.; Western Reserve University, Cleveland, 1876; aged 63; a member of the Kansas Medical Society; died, January 23, from chronic nephritis.

William H. Clarkson, Blair, Okla.; Memphis (Tenn.) Hospital Medical College, 1889; aged 58; a member of the Oklahoma State Medical Association; died, December 13.

Otto James Blessin, Galesburg, Ill.; Hahnemann Medical College, Chicago, 1901; aged 40; captain, M. R. C., U. S. Army, and discharged, Jan. 18, 1919; died, January 29.

James Emmett Vaughan * Lynchburg, Va.; Lincoln Memorial University, Knoxville, Tenn., 1893; aged 60; died, Dec. 18, 1919, from chronic interstitial nephritis.

William A. Paschall, Franklin, Tenn.; Vanderbilt University, Nashville, Tenn., 1881; aged 60; died at the Woman's Hospital, Nashville, January 31, from pneumonia.

John Alexander Landis, Oklahoma City; University of Tennessee, Nashville, 1860; aged 82; died at the home of his daughter in Brownsboro, Texas, January 24.

Joseph William Martin, DuBois, Neb.; University of Nebraska, Omaha, 1903; aged 52; died at the home of his mother in Pawnee City, Neb., January 23.

Charles Ash Bower * Mitchell, S. D.; Hahnemann Medical College, Chicago, 1900; aged 44; was drowned while bathing at Lake Worth, Fla., January 21.

Caleb F. Elkins, Liege, Mo.; American Medical College, Eclectic, St. Louis, 1901; mayor of Liege and health officer of Montgomery County; died, January 26.

John F. Shaw, Wilkes-Barre, Pa.; Medico-Chirurgical College of Philadelphia 1895; aged 66; also a druggist; died, February 1, from cerebral hemorrhage.

William Gwathmey, Beulahville, Va.; Medical College of Virginia, Richmond, 1898; aged 40; a member of the Medical Society of Virginia; died, January 5.

Edward Hills Lake, San Francisco; St. Louis College of Physicians and Surgeons, 1895; while on his return from Australia, died at sea, January 28.

Patrick James Hughes, Lawrence, Mass.; University and Bellevue Hospital College, 1907; aged 41; died, January 26, from pulmonary tuberculosis.

Robert G. Langsdale, Middletown, Ohio; Medical College of Ohio, Cincinnati, 1881; aged 71; died in the Middletown City Hospital, January 26.

H. Moses Brooks, Olivebranch, N. C.; University of Maryland, Baltimore, 1879; aged 64; died, January 21, in a hospital in Charlotte, N. C.

John M. Grant ♂ St. Louis; Missouri Medical College, St. Louis, 1889; aged 55; a specialist in surgery; died, January 29, from pneumonia.

A. Malen Spangler ♂ Pageton, W. Va.; College of Physicians and Surgeons, Baltimore, 1892; aged 53; died, January 18, from diabetes.

Joseph L. Anderson, Tarentum, Pa.; College of Physicians and Surgeons, Baltimore, 1883; aged 65; died, January 27, from pneumonia.

James T. Parker, Chauncey, Ga.; Southern Medical College, Atlanta, 1897; aged 44; died in a hospital in Macon, Ga., January 30.

Joel J. Foulon ♂ East St. Louis, Ill.; Missouri Medical College, St. Louis, 1887; aged 57; died, January 23, from heart disease.

John Maynard Gulick, El Paso, Ill.; Northwestern University Medical School, 1891; aged 53; died, January 15, from endocarditis.

Nicholas R. Marshall, Evanston, Ill.; Rush Medical College, 1867; aged 76; a veteran of the Civil War; died, February 3.

Alban Thomas Cuzner, Gilmore, Fla.; College of Physicians in the City of New York, 1864; aged 80; died, January 18.

Edward Martin Cherry, San Francisco; Cooper Medical College, San Francisco, 1899; aged 46; died, about January 30.

Cyrus V. Luke ♂ Woodworth, Ill.; Illinois Medical College, Chicago, 1899; aged 44; died, January 16, from brain tumor.

Joseph Talbot Maclean, New York City; Bellevue Hospital Medical College, 1876; died, January 28, from pneumonia.

John M. Pierce, Rogersville, Tenn. (license, Tennessee, 1889); aged 73; for many years a druggist; died, December 16.

Archibald Gooding Servoss, Havana, Ill.; Jefferson Medical College, 1886; aged 54; died, January 22, from gastric ulcer.

Oliver Frank Harper, Baltimore; Atlanta (Ga.) School of Medicine, 1911; aged 30; also a chemist; died, January 22.

Emory Lanphear, St. Louis; Missouri Medical College, St. Louis, 1881; aged 60; died, in Citrus Park, Fla., February 6.

Philip Gray Sanderson, Detroit; University of Illinois, Chicago, 1899; aged 53; died, January 28, from pneumonia.

Ralph Emerson Buck, Newfield, N. J.; Rush Medical College, 1894; aged 49; died, February 4, from acute gastritis.

James A. Fraser, Lexington, Mich.; University of Vermont, Burlington, 1886; aged 60; died, about January 29.

L. C. Goneke, Springvale, Ga.; Atlanta (Ga.) Medical College, 1884; aged 60; died, January 27, from dysentery.

Frederick Woodhull, Hartney, Man.; Trinity Medical College, Toronto, 1886; aged 56; died in October, 1919.

Walter Westlake Hoare, Walkerville, Ont.; Queens University, Kingston, Ont., 1864; aged 83; died, January 29.

Samuel L. Inman ♂ El Paso, Texas; Marion-Sims College of Medicine, St. Louis, 1897; aged 54; died, recently.

Edmund B. Echlin, Ottawa, Ont.; Queens University, Kingston, Ont., 1891; aged 56; died, Dec. 12, 1919.

Sabritt Scruggs, Rolla, Miss.; Kentucky School of Medicine, Louisville, 1866; aged 80; died, January 27.

William Bilbro Palmer, Audubon, Texas; University of Nashville, Tenn., 1887; aged 70; died, January 21.

D. Luke Gavin, Shubuta, Miss.; Louisville (Ky.) Medical College, 1898; died in Chicora, Miss., January 31.

Frederick Roderick Dew, Weston, W. Va.; Baltimore Medical College, 1905; aged 40; died, January 31.

Daniel Justin McSweeney, Boston; Harvard University Medical School, 1903; died, about January 20.

Renwick W. Bartley, Marion, Ind.; Loyola University, Chicago, 1880; aged 74; died, January 25.

James T. Croney, Lima, Ohio (license, Ohio, years of practice, 1896); aged 75; died, January 21.

Nicholas J. Hopkins, Dunnville, Ont. (license, Ontario, 1869); aged 77; died, Nov. 7, 1919.

P. W. Logan, Knoxville, Tenn.; Jefferson Medical College, 1861; aged 80; died, January 28.

J. C. Barker, Lebanon, Mo. (license, Missouri, 1884); aged 84; died, January 18.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

EUMICTINE

Report of the Council on Pharmacy and Chemistry

The Council has adopted and authorized publication of the report which appears below. This report declares "Eumictine" ineligible for New and Nonofficial Remedies because (1) it conflicts with Rule 10 in that it is unscientific and useless, (2) it conflicts with Rule 6 in that it is sold under unwarranted therapeutic claims, (3) it conflicts with Rule 4 against indirect advertising to the public in that the name "Eumictine" is blown in the bottle for the obvious purpose of bringing the product to the attention of the public when it is prescribed in the original package and (4) because the name is therapeutically suggestive and not in any way descriptive of its composition.

W. A. PUCKNER, Secretary.

Eumictine is a preparation from the laboratory of Maurice Le Prince, Paris, France, and is marketed in this country by George J. Wallau, Inc., New York. It is claimed that the product is "a balsamo-antiseptic preparation composed of Santalol, Salol, and Hexamethylene-Tetramine, in the form of gluten-coated capsules." Nowhere in the advertising are the amounts of the ingredients given. According to the American agent, however, "each capsule is supposed to contain 20 centigrams of Santalol, 5 centigrams of Salol, 5 centigrams of Hexamethylene-Tetramine."

Eumictine is advised "in treating genito-urinary diseases (urethritis, cystitis, prostatitis, pyelitis, etc.)." It is claimed to be "both an antiphlogistic modifying agent, a well-tolerated diuretic" which "may be administered for long periods without ill effects."

The Council declares Eumictine ineligible for New and Nonofficial Remedies because it is exploited in conflict with the following rules:

It is unscientific (Rule 10). Eumictine is composed of hexamethylenamin, salol and santalol in fixed proportions. Hexamethylenamin may serve a useful purpose in some forms of infection of the urinary tract, but neither it nor salol are of any considerable value in gonorrhea. It is now known that the balsamic preparations, formerly so widely used, do not have the curative effects in gonorrhea and associated conditions that used to be ascribed to them. To combine three substances, none of which has any distinct therapeutic value in the conditions for which Eumictine is proposed, does not enhance their value. There is nothing original in the combination used in Eumictine, or in the manner of dispensing it.

It is sold under unwarranted therapeutic claims (Rule 6). These claims are made not only for the components of Eumictine but for the combination itself. Though santalol has certain advantages over the somewhat variable oil of santal and other balsamic resins, it is not true that santalol "does not cause congestion of the renal epithelium" or that it does not "produce exanthema as do copaiba, cubebs, and the ordinary santal oil." It is not true that salol is "devoid of toxicity." Neither is it correct to say that salol "asepticizes and disinfects the bladder, the prostate and the urethra." The claim that hexamethylenamin "is of value when any acute symptoms or tendency to inflammation subsist" is not justified. The claim that hexamethylenamin "renders soluble the uric acid and urates" is also without foundation. The fol-

lowing paragraph is characteristic of the claims made for Eumictine:

"Anti-gonorrhoeic by its Santalol, diuretic, urolytic and analgetic by its hexamethylenetetramin (Urotropin) antiseptic and antipyretic by its Salol, Eumictine represents a real therapeutic advance in the scientific treatment of diseases of the urinary passages."

Instead of being "a real therapeutic advance" in the treatment of diseases of the urinary passages, Eumictine presents one of the complex combinations that have long retarded the scientific treatment of these diseases. Eumictine also conflicts with Rules 4 and 8 of the Council.

Correspondence

NEED OF UNIFORMITY IN SHAPE AND SIZE OF PROFESSIONAL REPRINTS AND ADVERTISED OBJECTS

To the Editor:—There should be uniformity in the size, shape and arrangement of printed data that the physician may wish to preserve, conveniently file and promptly refer to. This should include (a) reprints of papers and (b) advertising data describing objects that deserve preservation and prompt reference.

The object of collectanea is convenience for filing and for reference. I have previously made recommendations to advertisers that they adopt a suitable system whereby descriptive matter, memoranda, etc., could be readily filed. One measure has been extensively adopted, viz., index filing cards of a standard size, 3 by 5, also small, closely printed circulars or descriptive booklets of the same size and containing several pages of outline. The fact is that many physicians now use index filing systems, kept in the drawer of a desk for short case notes, and another for other data. Inquiry and experience teaches me that this custom of filing data is becoming nearly universal, and will become more so in proportion as the material is supplied in filable shape. Meanwhile, all heterogeneous printed stuff in odd sizes and forms is thrown in the scrap, where it deserves to go. Contemplate the millions of money thus wasted. (One comes to doubt gravely the commercial wisdom of many big business bodies.)

Reprints of valuable articles suffer in much the same way. To collect and attempt to arrange them causes suffering, vexation and loss of time to those who wish to preserve and later read them. Surely all editors or managers of medical journals should be as wise, or at least as cooperative, as some manufacturing concerns have now become. This subject is no trifling matter; it is of fundamental significance.

J. MADISON TAYLOR, M.D., Philadelphia.

"VACCINATION WITHOUT SCAR"

To the Editor:—In a recent editorial comment (THE JOURNAL, Jan. 24, 1920, p. 252), reference was made to Major J. R. Goodall's paper on "The Subcutaneous Method of Vaccination," under the caption, "Vaccination Without Scar." The experiment recorded by Goodall in his paper does not give exact information, which is necessary before any conclusions can be drawn. Six thousand individuals were each given, subcutaneously, from one quarter to three quarters of the contents of a capillary tube of vaccine with sufficient water added to make 1 c.c. The local reaction was described as being very similar to that resulting from the injection of typhoid vaccine. The reaction, however, did not appear in the majority of cases till after the second day. This was occasionally delayed till even the tenth day. No reaction was reported in 8 per cent. of the cases. In a few cases the reaction was marked, causing swelling of the elbow, and in some the edema involved the whole arm and hand. Between the seventh and tenth days the local swelling and induration subsided, leaving a hard nodule ill defined, which later became well circumscribed and persisted for

about one month. The general symptoms varied in intensity and did not differ from those of ordinary vaccination. No mention, however, is made of different reactions being observed in the cases of men previously vaccinated, which is regretted. An omission which is most vital to the subject was the revaccination of some of those who had received the vaccine by the ordinary method. This would have given evidence as to the immunity produced. Without such further observations, accurate deductions cannot be drawn.

Finally, the wisdom of the subcutaneous injection of vaccine virus which, under ordinary circumstances, contains living bacteria is open to question. The bacterial count of vaccine virus (Hygienic Laboratory standards) may be as high as fifty bacteria per capillary tube. Goodall used from one quarter to three quarters of the contents of the capillary tube, and even if smaller amounts are used, this objection remains.

R. D. DEFRIES, M.D., Toronto.

"HITHERTO UNDESCRIBED DISLOCATION OF THE PATELLA ENDWISE"

To the Editor:—There is nothing new under the sun. In THE JOURNAL, Feb. 7, 1920, p. 388, there appeared under the heading "Hitherto Undescribed Dislocation of the Patella Endwise," a report of a case of horizontal rotation of the patella due to laceration of the quadriceps tendon. Such an injury has not hitherto escaped observation and description, as the author would indicate, but, on the contrary, is described in many textbooks on general surgery and in monographs on fractures and dislocations. Such cases are very rare, but have been known to occur for many years. Reference to this injury will be found in Stewart's "Manual on Surgery," page 316; Wharton and Curtis' "Practice of Surgery," page 598, Keen's "Surgery," Volume II, page 427; Wyeth's "Surgery," page 200; and it is described very fully and reported cases are cited in Stimson's work on "Fractures and Dislocations."

JOHN H. GIBBON, M.D., Philadelphia.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

GOLAY'S MODIFIED WASSERMANN REACTION

To the Editor:—Could you give me information about the simplified serologic test of J. Golay, appearing in THE JOURNAL, Jan. 31, 1920, p. 361. Could you give me the technic?

PAUL SERRE, M.D., Dixmont, Pa.

ANSWER.—Golay's modification of the Wassermann reaction is based on the antihuman hemohemolytic method of Noguchi (THE JOURNAL, April 20, 1918, p. 1157). The antigen is furnished by an alcoholic extract of the liver from congenital syphilis. Complement is obtained from a rabbit immunized by injection of 10 c.c. of a 10 per cent. suspension of human corpuscles in physiologic sodium chlorid solution. The serum is inactivated by heating over a water bath at 56 C. for one hour. The amoceptor is titrated as follows: Into each of a series of tubes are put 1 c.c. of physiologic sodium chlorid solution, two drops of human serum and 0.5 c.c. of a 5 per cent. suspension of blood corpuscles. Progressive doses (one, two, three, etc., drops) of rabbit serum are added to the various tubes. The titer of amoceptor is the smallest quantity that will produce complete hemolysis after incubation over a water bath at 37 C. for one-half hour. The antigen is titrated in the same way by using the requisite quantity of amoceptor as determined in the foregoing. For preparing the suspension of blood corpuscles the defibrinated blood of the patient is washed with physiologic sodium chlorid solution until it is free from serum and the wash water is absolutely clear. The technic of the test is as follows: In the first tube (syphilitic system) are put 1.1 c.c. of physiologic sodium chlorid solution, the requisite drops of antigen, and two drops of the patient's serum; in the

second tube 1.2 c.c. of physiologic sodium chlorid solution and two drops of the patient's serum. The tubes are incubated at 37 C. for one hour. The requisite number of drops of amboceptor and 0.5 c.c. of a 5 per cent. suspension of corpuscles (hemolytic system) are then added to each tube; these are incubated until complete hemolysis of the control. The tubes are centrifuged and the results are read. It is advisable to use two doses of antigen for each test; one the maximum titer, the other dose sensibly less. Three tubes will then be necessary instead of two. The test should be made as soon as possible after obtaining the patient's blood.

THERAPEUTIC VALUE OF DIGITALIS

To the Editor:—Please refer me to the recent literature on the therapeutic value of digitalis as disclosed by recent investigations and tests.

J. A. SPEED, M.D., Durham, N. C.

ANSWER.—The literature contains a vast number of articles pertaining to digitalis; a general discussion of digitalis may be found in such recent works as Frederick Forchheimer's "Therapeutics of Internal Diseases," edited by Frank Billings and E. E. Irons; "A Manual of Pharmacology," by Torald Sollmann, or "Useful Drugs," published by the Council on Pharmacy and Chemistry. The subjoined references are to some of the leading articles of the last ten years:

In addition to the foregoing, two reports by the Council on Pharmacy and Chemistry (*THE JOURNAL*, Sept. 5, 1914, p. 881, and Dec. 4, 1915, p. 2024) and also a number of short reports and abstracts appearing in the November, 1919, issue of the *Journal of the American Pharmaceutical Association* (pp. 900 to 928) should be consulted.

INTRAVENOUS ADMINISTRATION OF SODIUM SALTS IN COMBINATION

To the Editor:—Can you tell me whether it is safe to give sterile solution of sodium salicylate and sodium iodid intravenously? Is their combination compatible with the blood stream without any special preparation? If it requires special preparation and cannot be made up by the practitioner or ordinary pharmacist, can you inform me of any reputable preparation for use?

W. D. CHASE, M.D., Bethlehem, Pa.

ANSWER.—The danger from the intravenous administration of solutions of sodium salicylate or of sodium iodid are those inherent in the intravenous method of drug administration. Since the effect of salicylates and of iodids may readily be attained by oral administration of sodium salicylate or other salicyl preparations, and of sodium iodid or one of its substitutes, the intravenous administration is rarely, if ever, necessary or warranted. Solutions for intravenous use must be sterile, but pharmacists should have little difficulty in furnishing satisfactory products. The objections to the unnecessary use of the intravenous method of administering drugs were discussed in *THE JOURNAL*, Nov. 11, 1916, p. 1450. The intravenous administration of salicylates was discussed in *THE JOURNAL*, Oct. 28, 1916, p. 1319.

"THE NEW DU PONT ETHER"

To the Editor:—Please let me know what information you have about the enclosed clipping.

E. W. CARPENTER, M.D., Greenville, S. C.

To the Editor:—"Cotton Process Ether," manufactured by the Du Pont Co., has been given considerable notoriety in the lay press. A letter of inquiry addressed to the firm elicits the information that "Cotton Process Ether is a very highly refined Di-ethyl Ether charged with Ethylene Gas." . . . What is your opinion of the "Cotton Process Ether"? Has the Council on Pharmacy and Chemistry investigated this product?

JOHN L. ATLEE, M.D., Lancaster, Pa.

To the Editor:—I have been waiting for some reference to the new anesthetic referred to in the enclosed clipping, but if any has been made in the medical press I have failed to notice it. If there is anything of interest in connection with this item, and it is not too much trouble, I will thank you to put me in touch with the situation.

HOLMAN TAYLOR, M.D., Fort Worth, Tex.

ANSWER.—About January 20, the "News Service" of the "E. I. Du Pont De Nemours and Co., Inc.," circularized the press of the country with what it was pleased to term a "good 'filler'"; this particular piece of press agent work dealt with "The New Du Pont Ether." To quote one paragraph from the "News Item":

The new anesthetic, which is a highly refined di-ethyl ether, modified by the addition of gases, has the following characteristics: (1) the property of inducing and maintaining anesthesia with practical freedom from postoperative nausea, and (2) the property of inducing and maintaining analgesia (conscious insensibility to pain) as distinguished from anesthesia (insensibility to pain plus narcosis).

The Du Pont Ether and the claims made for it are seemingly based on the work of one man, "James H. Cotton, M.A., M.D., Toronto, Canada," who published an article on "Cotton Process Ether and Ether Analgesia," in the *American Journal of Surgery* for April, 1919. However, Cotton did not give the composition of the "new" ether nor, so far as we are aware, has his work been corroborated. In view of the inquiries received, the Secretary of the Council on Pharmacy and Chemistry asked the Du Pont Chemical Works for the composition of the new ether. From the firm's reply we quote one paragraph:

" . . . The procedures of manufacture, and the exact composition of our ether, we regard as confidential information which we are entitled to retain unless a condition were to arise in which we were unable alone to satisfy the demand for this type of ether."

It has been recognized—and incorporated in the "Principles of Medical Ethics"—that the use of a therapeutic agent of unknown composition is unscientific and contrary to the best interests of the medical profession and the public; but it is many times more serious for a physician to employ a secret or semisecret substance as an anesthetic. A physician using such a semisecret substance would have little defense if the patient should die.

VERONAL (BARBITAL) ADDICTION

To the Editor:—Can you give me information about veronal addiction? I have a patient who is addicted to this drug, but I cannot find much in the literature about veronal addiction and its treatment. He has taken treatment at several hospitals, but they always send him out using his veronal. This case might be interesting to the medical profession, as veronal is being used a great deal by them at present.

A. B. C.

ANSWER.—Constant use of even small doses of barbital (veronal) affects the central nervous system, especially the cerebellum and the vestibular portion of the cochlea. Those taking the drug habitually become much debilitated and seem less able to stand moderate doses. Death has occurred from a 3 gm. dose in addicts, while recoveries are known after a single dose of 10 gm. in others. Fog (*Ugesk. f. Læger* 79:370 [March 8] 1917) treated a case of addiction by gradually substituting antipyrin salicylate in the powders which were being taken until the patient was getting no barbital at all. In England barbital and its closely related derivatives have been classed as poisons, and as such are subject to the same regulations that apply to the sale of narcotics.

PELVIC VARICOCELE

To the Editor:—Please give a notation of recent literature on varicose veins of the broad ligament.

W. F. SIHLER, M.D., Devils Lake, N. D.

ANSWER.—The following references are taken from the Quarterly Cumulative Index:

- Wall, J. A.: Pelvic Varicocele, *Surg. Gynec. & Obst.* **23**: 62 (July) 1916.
Darnall, W. E.: Varicocele in the Female, *Med. & Surg.* **1**: 624 (Aug.) 1917.
Jewett, W. A.: Pelvic Varicocele, *Am. J. Obst.* **75**: 500 (March) 1917.
Furniss, H. D.: Pelvic Varicocele, *Am. J. Obst.* **75**: 152 (Jan.) 1917.

Book Notices

CONTRIBUTIONS TO MEDICAL AND BIOLOGICAL RESEARCH. Dedicated to Sir William Osler, Bart., M.D., F.R.S., in honor of his seventieth birthday, July 12, 1919, by his pupils and co-workers. Two volumes. Pp. 1268. Paul B. Hoeber, New York. Edition limited to 1,600 copies.

In these two large octavo volumes have been collected essays by some of the numerous pupils and co-workers of the late Sir William Osler. They are issued as a tribute to him on his seventieth birthday. The 142 essays are contributed by 151 writers, including 106 American, 33 English, 10 Canadian and 2 Scotch physicians; they are scientific, historical and literary. As might have been expected of such a large number of articles, there are variations in quality. Some are notable, others unusually good, and some of ordinary character. A few—happily only a few—are not quite worthy of a place in this series. In general, it may be said that the articles on historical, educational and social subjects distinctly surpass in literary quality and general interest those of a scientific or clinical nature. This is perhaps accounted for by the very nature of things, since the research worker or clinician could not produce a special study for this purpose, but must needs report work already done and use something already published, or, perhaps, rewrite for this purpose.

The first volume opens with a frontispiece—a steel engraving of Sir William Osler—an excellent likeness. Following is a beautiful proem by Sir Clifford Allbutt. In an editorial note the committee states the purpose and method of preparation of these volumes. The first twenty-eight essays are by British and Canadian physicians. Mr. Acland, in the first article, describes the Oxford University Museum. The article is well illustrated with especially fine half-tone photographs of the museum, and is a most interesting account of the relation to this museum of some of the predecessors of Sir William Osler in the chair of medicine at Oxford. It is brought out that John Ruskin was in part responsible for the designing of this structure. The second essay is a timely discussion of graduate study in London by Professor Adami, who is well adapted to the task, through his Canadian experience, his experience in the world war, and his intimate knowledge of conditions in America. Following two historical essays are some personal reminiscences of Sir William Osler by Dr. Crozier describing the early life of the great teacher.

A notable essay is that of Sir Auckland Geddes, entitled, "Social Reconstruction in the Medical Profession." Sir Auckland is intimately associated with reconstruction programs in Great Britain and is largely responsible for the establishment of the Ministry of Health. His views, therefore, are of great importance. It is interesting to note that in his opinion "the medical profession in Great Britain, with brilliant exceptions, is in the main composed of men who are immature as citizens, and in quite a separate compartment of their being possess expert technical knowledge, too often on sale to the highest bidder."

As is usual with his writing, Dr. Arthur Keith contributes a notable historical essay on the Hunterian School. Most fascinating is a description by Dr. Macalister, secretary and editor of the Royal Society of Medicine, of an institution which exists in medical Utopia, the Osler Library. This institution, which the author has visited in his dreams, is the

medical library *par excellence*. The essay must be read to be appreciated. Librarians will overlook a great opportunity if they fail to adopt some of Dr. Macalister's suggestions.

As is usual also, Sir Humphrey Rolleston contributes a notable essay on Thomas Trotter, physician of the Grand Fleet in 1780. The well known historians, Charles and Dorothea Singer of Oxford, describe a miniature depicting an operation. The miniature is beautifully reproduced in colors.

There follow essays on some seventeenth century writings on the endowment of research, on Galen, Plato and Immortality, and on "Fragment of a Persian Primer." Sir Clifford Allbutt discusses "Innate Heat."

The next essay has the fascinating title, "On the Sizes of Things, or the Importance of Being Rather Small," which develops into a discussion of the coleoptera and the reaction of bacteria on the human organism. A most interesting essay is that of F. Parkes Weber, "Thinking and Dreaming, and the Explanation of Dreams." Those acquainted with his notable book on the "Aspects of Death" will find this essay all that might be expected of the author.

Professor Anders writes on "Myxedema and Cretinism"; Dr. C. C. Bass on "Malaria"; Dr. Norman Bridge has a note on "Pulmonary Streptothricosis" as observed in California; Dr. N. S. Brill of New York writes on "Typhus Fever"; Dr. Thomas Cullen of Baltimore describes a special sign noted in the umbilicus; Dr. Edsall describes poisoning with manganese as it occurs in the industries. All of these essays, as those familiar with medical literature know, concern subjects which have interested their writers for many years and in which they have made notable advances.

The second volume opens with a discussion by Dr. Frank Billings on the "Rehabilitation of the Disabled." Brigadier General Munson has a brief essay on "Military Morale." Dr. C. L. Dana, who acted as editor, contributes an essay, "A Psychotic Episode in Roman History." The late Mortimer Frank has an interesting historical article, and Dr. Fielding Garrison a charming essay entitled, "Physicians' Letters." Very timely is the note by Guy Hinsdale describing epidemics of influenza in 1647, 1789 and 1807 as they were recorded by Noah Webster, Benjamin Rush and Daniel Drake. Particularly interesting is a note by Dr. Henry Hurd on Sir William Osler's relation to the Johns Hopkins Hospital, a note no one would be more fitted to write; and in the same manner, Dr. George M. Kober discusses the influence of Osler on American medicine. Space forbids even a mention of all the articles and authors. One interesting article follows another, promising the reader many valuable hours with these valuable essays; reminding him of the greatest work which any great physician can do, the instruction of students, leading to the production of great thinkers who will follow in his footsteps.

Mechanically, the books are excellent, printer and publisher having done their work well. There are many half-tones of artistic and historical merit. The selection of the type, the spacing, paper and binding could hardly have been improved on. The delay in publication, due to the long printer's strike in New York, was unfortunate and unavoidable. It was especially unfortunate because the books in their final form reached Oxford only two days before Sir William's death. These volumes represent a large amount of labor on the part of the committee, which may well take pardonable pride in the results of their efforts.

GUN-SHOT FRACTURES OF THE EXTREMITIES. By Joseph A. Blake, Lieutenant-Colonel, Medical Corps, U. S. A. Paper. Price, 4 francs. Pp. 136, with illustrations. Paris: Masson et Cie, 1918.

While this little book is essentially a work on war surgery it contains much that may prove of value to the surgeon in civil life, particularly with regard to the application of splints, bandages and extension apparatus to compound fractures. Virtually all the material presented has been described and discussed repeatedly in every surgical journal of consequence during the past three years, so that it should be fairly familiar. Nevertheless, those who desire an authoritative summary of the subject will find it here with sufficient details for general guidance.

Medical Education, Registration and Hospital Service

COMING EXAMINATIONS

ALASKA: Juneau, Mar. 2. Sec., Dr. L. O. Sloan, Juneau.
ARIZONA: Phoenix, April 6-7. Sec., Dr. Ancil Martin, 207 Goodrich Bldg., Phoenix.

COLORADO: Denver, April 6. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.

CONNECTICUT: New Haven and Hartford, March 9-10. Sec., Reg. Bd., Dr. Robert L. Rowley, Hartford. Sec., Homeo. Bd., Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven. Sec., Eclectic Bd., Dr. James Edwin Hair, 730 State St., Bridgeport.

FLORIDA: Jacksonville, March 16. Sec., Homeo. Bd., Dr. Geo. A. Davis, East Port.

IDAHO: Boise, April 6. Commissioner, Hon. Robert A. Jones, Boise.
ILLINOIS: Chicago, Mar. 1-3. Director, Mr. Francis W. Shepardson, Springfield.

IOWA: Iowa City, March 29-31. Sec., Dr. Guilford H. Sumner, Capitol Building, Des Moines.

MAINE: Portland, March 9-10. Sec., Dr. Frank W. Searle, 140 Pine St., Portland.

MASSACHUSETTS: Boston, March 9-11. Sec., Dr. Walter P. Bowers, Room 144, State House, Boston.

MINNESOTA: Minneapolis, April 6-8. Sec., Dr. Thos. McDavitt, Loury Bldg., St. Paul.

MONTANA: Helena, April 6. Sec., Dr. S. A. Cooney, Power Bldg., Helena.

NATIONAL BOARD OF MEDICAL EXAMINERS: St. Louis and Chicago, Feb. 18-25. Sec., Dr. J. S. Rodman, 1310 Medical Arts Bldg., Philadelphia, Pa.

NEW HAMPSHIRE: Concord, March 11-12. Sec., Dr. Charles Duncan, Concord.

OKLAHOMA: Oklahoma City, April 13-14. Sec., Dr. J. M. Byrum, Shawnee.

RHODE ISLAND: Providence, April 1-2. Sec., Dr. Byron U. Richards, State House, Providence.

WEST VIRGINIA: Charleston, April 13. Sec., Dr. S. L. Jepson, Masonic Bldg., Charleston.

GRADUATE MEDICAL EDUCATION

J. M. ANDERS, M.D., LL.D.
PHILADELPHIA

The present position of undergraduate medical education in this country may be said to be satisfactory as the result of systematic efforts at standardization, although the principle that related departments should work together in order that the various problems connected with individual diseases may be viewed at once by the student needs to be more widely applied. On the other hand, graduate training has not been developed to a commendable extent. Before indicating some lines of reform in graduate training, it might be well for me to recite a few fundamental facts which show the vastness of the problem and also the needs of the large number of practitioners and specialists who present themselves for instruction.

THE GENERAL PRACTITIONER AND THE NEEDS OF THE COMMUNITY

The busy physician cannot keep pace with the remarkable and continuous additions to our knowledge of the modern methods of diagnosis and treatment, as well as the prevention of disease and the laboratory technic. Many of those who seek help enjoyed meager opportunities for the study of the basal sciences and clinical training while at a medical college, not to speak of the well known paucity of laboratory facilities. Now the aim and purpose of graduate teaching should be primarily to maintain an adequate medical service, and to accomplish this the needs of the general practitioner must be fully recognized. But though modern movements in the practice of medicine are everywhere evidenced by a tendency toward specialization, the general practitioner has not been displaced. Says Lyon¹ in this connection: "I predict that general practice will endure, will adjust itself to specialization and to group medicine and to public medicine."

Among those vitally interested in postgraduate medical education are some who would restrict training to the higher grade of practitioners and to those who desire instruction in special subjects as well as in the medical specialties. By exacting certain entrance requirements, they would exclude a large contingent of medical practitioners who apply for needed help: they would, in short, practically abandon the so-called polyclinic courses. It seems to me that ways and means should be found to assist all classes of physicians, excepting the so-called hopeless cases. Requirements for acceptance should be waived in the case of those who are in good standing and who merely wish to improve their diagnostic and therapeutic skill by taking an intensive practical course. It has been well said that the general practitioner is the foundation of any medical service, its "first pivot, its anchor, its instrument."

The creation of the Medical Reserve Corps of the army during the recent world war disclosed a not inconsiderable class of physicians who were professionally inefficient; but many of these finally reached the medical training camps after being subjected to a process of filtration. It seems to me that owing to the care and caution exercised by the Surgeon-General to make certain that all medical officers receiving appointment were men of good professional standing and fair attainments they should be admitted to the polyclinic and other courses of our graduate schools without examination or preliminary test of any sort. Munson² points out that for many of those not found qualified, special schools and "salvage classes" were organized, and they were thus rendered competent for efficient military duty. The war having taught us the great value of practical and intensive courses in preparation for commissions in the army and navy, it is obvious that brief polyclinic courses (e.g., of four months as the minimum) should hold a definite place, for the present, at least in our graduate schools, so as to qualify the professionally inefficient for civilian service.

One factor which bears specifically on this aspect of the subject is the precept that above the interests of the medical school for graduates stand the interests of the general public. These interests may not be ignored in planning the scope and curriculums of our postgraduate institutions. There was a time, easily recollected by the majority of the present generation of physicians, when in our undergraduate schools, the courses in pathologic anatomy, including the performance of necropsies, in microscopy, physical diagnosis, laboratory methods, in bedside clinical training and other branches were on a scale far from commensurate with their importance. The men and women who were graduated under the old order of things, and the same may be said of all who have been engaged in general practice for a few years even, cannot, as stated above, keep abreast with the more recent and continuous advances of enormous significance to the communities in which they carry on their professional work. Shall these general practitioners be denied an opportunity to acquire modern methods which will enable them to diagnose and attack disease with greater assurance of success? Is it not reasonable to assume that it is the duty of graduate schools to make provision for the immediate needs of the public and of practicing physicians who recognize and seek to remove their deficiencies, the while indulging the hope that one day this demand will be less insistent or may cease to exist altogether?

There is another and hopeful phase of the situation to be observed in the present-day recognition of the importance of correlating the teaching of the basal sciences with the more strictly practical branches of medicine. Many of the

1. Lyon, L. P.: Graduate Education in the Clinical Branches, and the Minnesota Experiment, J. A. M. A. 69:1307 (Oct. 20) 1917.

2. Munson, E. L.: The Needs of Medical Education as Revealed by the War, J. A. M. A. 72:1050 (April 12) 1919.

difficulties and much of the confusion experienced by the undergraduate student will disappear, once he clearly appreciates the relationship that the various scientific subjects bear to one another and to clinical medicine.

The same precept applies with equal force to postgraduate teaching; and in order to accomplish a satisfactory correlation of the different branches it is necessary to have an organization based on a comprehensive knowledge of the practical interrelations of the branches represented in the curriculum. Such a scheme of coordination of the instruction is possible only with physicians who have given the subject of the arrangement of the graduate school curriculum careful and thorough study. Moreover, cooperation between the heads of the different departments and the deans of the various schools is essential to the end that appropriate teamwork may be effected. It is in line with the need of meeting this requirement of the graduate student that a most important reform is possible; but obviously it will demand time and serious thought to bring it about.

Doubtless, the further development of an adequate scheme of graduate medical education in this country will be in large part the result of the efforts of the American Medical Association. As in the case of undergraduate education, so in that of graduate training, the recommendations of special committees of this body, with the object of standardizing instruction, will be generally accepted. It may be reasonably assumed that candidates will be subjected to a process of elimination; but it is hoped and believed that this sifting will not exclude the medical graduates who compose the backbone of the profession and whose deficiencies are, in many cases at least, attributable to low standards of the medical schools from which they were graduated.

There should be brief, intensive courses, then, for the average general practitioner; they are an effective help in his work, and at the same time meet in a measure at least the needs of the community. Indeed, this educational movement is so largely associated with the vital interests of the public that further comment regarding the duties and responsibilities of graduate schools in the matter would seem to be unnecessary. Surely, graduate medical schools should not wait until the people in general are so organized and enlightened that they can adequately express their professional needs. For these brief group courses no official certificate should be granted, although a statement issued by the dean setting forth that the candidate had taken certain polyclinic courses, with a mention of the duration of the period of study would be allowable.

THE SPECIALTIES

The world war revealed the scarcity of physicians who were qualified to render service along technical or "highly specialized lines." While there was an unprecedented demand for physicians of the highest attainments during that period, the experiences gained served to emphasize the necessity for improvement in both undergraduate and graduate medical education, so as to procure and maintain an adequate expert medical service.

It follows as a natural corollary from the foregoing statements that one of the chief functions of the graduate school is to provide an opportunity for the preparation of physicians for service requiring exceptional qualifications and the highest skill, as specialists, teachers and research workers. To those desiring to pursue the advanced courses, however, a strict psychologic rating should be applied; and all who fail to show the proper mental aptitude should be rejected. These entrance examinations are to be conducted by a competent specialist in neurology or psychology in conjunction with the dean.

I feel strongly that the time has arrived when we must free ourselves, by degrees if need be, from the custom of including among polyclinic courses, strictly speaking, the recognized medical specialties. They should fall either into the higher courses or into those leading to degrees, or the purely personal ones with a view to attaining to greater technical and practical efficiency along special lines and to become impregnated with the environmental atmosphere of a given teacher. To requests for personal tuition either in general medicine or surgery or the specialties, graduate schools must ever give heed; but the instruction should be conducted quite independently of any or all group courses, and no degrees should be granted.

The adoption of advanced courses to prepare men for the specialties in medicine would be a distinct and long step in advance, and a commendable asset in the movement to eradicate incompetents. This object, the standardization of the specialties, will not be attained so long as one or more brief polyclinic courses give physicians the right to assume the rôle of a specialist. For example, modern operations are on the whole comparatively safe; but far greater credit would accrue to the medical profession if the so-called leading operations in all departments of medicine requiring surgical procedures were performed only by the thoroughly trained, skilled and experienced surgeon.

The organization and standardization of advanced courses necessitate an immediate division of internal medicine and general surgery into several subbranches or specialties. Further details with regard to these two subjects would be beside the scope and purpose of this article, although it may be added that each subdivision should be provided with a full-time head, and that graduate schools require a large personnel of well-trained and experienced teachers. The progress of the science and art of medicine has been, doubtless, retarded by lack of preparedness on the part of physicians who have been pursuing special limited fields of civilian practice. More rigid training after the proper scientific preparation and certification for specialists is a most pressing public need and should engage the attention of our newly organized graduate medical schools. Both entrance requirements and curriculums would naturally differ in different medical specialties, but they must without exception be conducted under the higher scientific and practical standards.

METHODS OF TEACHING

It is in the graduate schools of this country that the cooperative or group method of studying disease, which is to be commended, must be properly rooted and developed. It is time that a satisfactory start be made in the higher courses leading to degrees, which should be a guarantee of exceptional attainments in preparation for the conduct of professional chairs or the practice of one of the recognized specialties, or for public health work; indeed, this should be undertaken as soon as proper facilities can be offered.

It is generally conceded that original research is to be encouraged by graduate rather than undergraduate schools; it can have no definite place in the curriculum of the latter because of two significant facts: first, lack of time to pursue original investigation successfully, and second, lack of qualifications to carry on such difficult and exacting work with promise of important and reliable results.

The custom of conducting group courses has its well-marked limitations. While it is feasible to give theoretical training (lectures, demonstrations and the like) to groups or classes of students, the practical work, which should make up the bulk of the course, should be in great part at least by individual contact of the student with patients and apparatus under supervisory instruction. In operative tech-

nic a student assistantship affords an excellent opportunity to gain practical information; the same remark applies to the student of internal medicine. The method of individual touch with apparatus and patients is indispensably necessary in the more advanced courses for which special degrees are offered. It will be seen that an abundance of clinical material and laboratory equipment is a prime requisite for carrying on such training. Its successful consummation, therefore, demands a large corps of competent teachers, and the affiliation with universities of all available hospitals, clinics, laboratories and museums. Such an affiliation of hospitals and clinics with universities, however, should be effected slowly and systematically. Indeed, the process should never be more rapid than is consistent with thorough organization and efficient, systematic teaching. The length of degree courses should not be less than from two to three semester years.

The chief primary aim and purpose of graduate schools being to provide highly skilled specialists, teachers and research workers, so far as they accomplish these ends will they become a potent factor in the era of production and construction on which America has recently entered. To promote a scheme such as outlined, however, an ample endowment fund is absolutely essential. Not only are new hospitals and laboratories required, but also endowed chairs. We are passing through a period in which "drives" have become popular and surprisingly successful. It has been authoritatively stated that the need of funds was never greater at our universities than at present, owing to plans looking to new developments in connection with the graduate medical schools and in other lines of endeavor. Since time is the essence of such an undertaking, it is hoped that "drives" will be made in the immediate future by the alumni and friends of the great American universities which have failed to do so in the past. It should be recollected in this connection that institutions which have received grants from the General Education Board have been those which have themselves contributed a certain amount. I am decidedly of the opinion that once the public, more especially the benevolently inclined portion, thoroughly understands what is the goal of these schools and that the welfare of the community is first, financial aid can be obtained through private philanthropy and from the state as well.

Much pertaining to both comprehensive planning and execution of the public demands in regard to medical service must obviously be left to the future. Meanwhile, all who are identified with the control and direction of graduate education should be intensely occupied with endeavors to meet the new and ever changing conditions of the times. This will necessitate the institution of new policies and methods which must be given proper direction, after the most thorough consideration of their wisdom. As the work progresses there must also be maintained close intercourse between the policy forming management, the deans and the faculties, if a real merit system of graduate medical education is to be expected.

FUNCTIONS OF THE GRADUATE SCHOOL

To recapitulate, the fully functioning graduate school should provide:

1. Polyclinic courses preferably of from four to eight months' duration for those pursuing general practice, who are desirous of overcoming their unavoidable deficiencies.
2. Advanced courses in the different departments of internal medicine, surgery and in the medical specialties for which degrees are offered, properly standardized and from two to three years' duration with an adequate standard of acceptance and an examination at the close of each scholastic year.
3. Personal courses under special arrangements with individual teachers, quite independently of any class or group instruction.

4. An abundance of material and laboratory space and equipment resulting in part from a gradual and careful affiliation of hospitals and clinics with universities, and a large corps of teachers with sharp division of duties and fixed responsibilities, including full-time professors as heads of departments in the advanced courses, with proper emoluments of their services.

5. A research bureau with separate organization to which the other departments defined above would naturally contribute candidates, subject to certain acceptance standards.

6. Large endowments to meet the conditions of the times; this is fundamental to all success. The people—the benefactors—must be fully informed of the purpose and aims of this modern educational product, as an aid to the securing of private and corporate endowment.

Idaho October Examination

Mr. Paul Davis, director, Bureau of License, Idaho Department of Law Enforcement, reports the written examination held at Boise, Oct. 7-9, 1919. The examination covered 13 subjects and included 130 questions. An average of 75 per cent. was required to pass. Twenty candidates were examined, all of whom passed. Six candidates were licensed by reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
George Washington University	(1915)	82.3
Chicago College of Medicine and Surgery	(1917)	83.2
Hahnemann Medical College and Hospital of Chicago	(1913)	86.3
Northwestern University	(1904) 83.8, (1907)	78
Rush Medical College	(1917)	81.2
University of Illinois	(1919)	85.3
State University of Iowa College of Medicine	(1903)	85.5
University of Kansas	(1917)	82.8
University of Maryland	(1915) 83.3, (1918)	83.2

Social Medicine and Medical Economics

THE DISPENSARY SITUATION IN NEW YORK CITY

Summary and Recommendations

BY THE PUBLIC HEALTH COMMITTEE OF THE NEW YORK ACADEMY
OF MEDICINE*

The Public Health Committee of the Academy of Medicine was organized, May 1, 1911. Its main purposes have been:

1. To maintain a bureau for the collection of facts in regard to public health, sanitation and hygiene.
2. To endeavor to establish an active cooperation with all public health activities in the city.
3. To keep the medical profession advised of current public health conditions.
4. To render to the public authorities and to the community at large an authoritative medical opinion on public health matters.
5. To undertake and suggest special researches looking to the solution of vital public health problems.
6. To make comparative studies of methods and results of public health activities in other cities, both in this country and abroad.
7. To utilize facts obtained by the study of public health and hospital conditions for practical application in the preparation of the annual municipal budget.
8. To assist actively the various departments of the city government which relate to public health and hospitals in the preparation of their tentative budgets.
9. To study the hospital and dispensary situation in the city with a view of making plans for their future development and in order to further the efforts for raising the standards of efficiency.

From the time of its organization the committee has carried out its program faithfully, as demonstrated in the annual summaries of its work. The sphere of action and influence of the committee has been widened from year to year, and it now occupies an important place in the public health affairs of New York. Two of the studies of the committee have already been published in *THE JOURNAL*.¹

I. CLINIC FACILITIES IN NEW YORK

According to the report of the state board of charities there are 153 dispensaries in New York City. In this number are included twenty-one tuberculosis, eight dental, ten eye and three rabies clinics of the department of health, and six school dental clinics maintained by the Children's Aid Society. Of the 105 dispensaries outside of the health department and school dental clinics, there are sixty-five outpatient departments of hospitals, thirty-four detached dispensaries and six college dispensaries. In addition, the health department maintains twelve venereal disease clinics (all but two advisory only), three occupational clinics and sixty baby health stations. Several private agencies maintain an additional number of milk stations.

The average number of persons treated annually in the dispensaries of the city has been one and a quarter million for the last five years, and the average number of treatments given is about four million, making an average of over three treatments per patient.

Over 2,000 physicians in New York City are giving their services to dispensaries, and in the vast majority of instances their services are not compensated. Approximately 69 per cent. of the physicians are associated with outpatient departments of hospitals, and the remainder, or about 31 per cent., work in the independent dispensaries. The dispensaries are open weekly for about 8,000 clinic hours. Most of the dispensaries are open during morning and early afternoon hours. The number of dispensaries open in the late

afternoon hours is very small, and the total number of evening hours during which the clinics function is only 213½, or a little over 2.5 per cent. of the total number of clinic hours per week.

There is evidently a sufficiency of dispensary facilities in New York City, and there will be no need for additional dispensaries for some years to come if the existing facilities can be utilized to a larger extent, and if, with a system of paying salaries to physicians, the dispensary hours can be arranged to meet in a larger degree the demand of those who are employed, and of the schoolchildren.

Of late the dispensaries have taken on functions along the lines of preventive medicine and public health, but this development is still in its infancy. The great opportunities of the dispensaries in the fields of both curative and preventive medicine have not as yet been fully grasped by the institutions, nor have their social responsibilities been clearly realized.

II. THE DISPENSARY LAW

According to the state law of New York, all persons applying for advice or treatment at a dispensary must be questioned as to their ability to pay a physician, and only those who are, in the opinion of the registrar, unable to pay physicians or dentists, shall be accorded treatment. Exceptions to the rule are permitted in emergency cases and cases of communicable disease (this refers chiefly to tuberculosis and venereal diseases), and in the case of persons applying at dispensaries connected with medical schools which may be "selected for use in clinical instruction." It is a misdemeanor to obtain medical or surgical treatment on false representation. The questioning concerning the financial status of dispensary applicants required by law is more or less perfunctorily performed; and although the law has been on the statute books for twenty years, not a single case has been brought to court.

Studies made at various times in several cities, including New York, show that the amount of imposition on the practically free services of dispensaries is not flagrant and does not constitute an important factor in the dispensary problem. The study conducted by a special committee of the New York County Medical Society in 1912² led to the conclusion that 10 per cent. of the patients seemed "able to pay for medical treatment under ordinary circumstances, but the margin over and above fixed expenditures seemed in most cases so slight that in illness demanding continued treatment or the services of a specialist, to pay a physician would mean for them serious deprivation or the incurring of debt from which afterward it would be difficult to escape."

A study of 1,000 cases at the Presbyterian Hospital Dispensary in Philadelphia showed that in 2 per cent. of the cases the acceptance of free care offered by the hospital amounted to abuse.³

The Illinois State Health Insurance Commission reported in May, 1919, that according to its study 4.5 per cent. of the dispensary patients "were recipients of medical charity which their economic status did not justify."⁴

Similar studies at the Boston Dispensary and at the Washington University Dispensary at St. Louis led to the conclusion that 2 per cent. of the patients were taking undue advantage of the free services of the dispensary physicians.⁵

Our own study, based on first hand information obtained from the patients who were visited in their homes, corroborates the findings of the other investigations. We found that 2.2

* The members of the committee are E. H. Lewinski Corwin, Ph.D., executive secretary; Dr. Charles Loomis Dana, chairman; Dr. James Alexander Miller, secretary, and Drs. John S. Billings, Nathan E. Brill, Robert J. Carlisle, James B. Clemens, Haven Emerson, Lewis Fox Frissell, Arpad G. Gerster, S. S. Goldwater, John A. Hartwell, Ward A. Holden, L. Emmett Holt, Otto V. Huffman, Walter B. James, Walter L. Niles, Bernard Sachs, Thomas W. Salmon, Frederic E. Sondern, M. Allen Starr, W. Gilman Thompson, Philip Van Ingen, Karl M. Vogel, George B. Wallace, Cassius H. Watson and Herbert B. Wilcox.

4. Report of Health Insurance Commission of the State of Illinois, May 1, 1919, pp. 93, 355.

5. Davis and Warner: Dispensaries, New York, 1918.

per cent. of the patients were palpably taking undue advantage of the dispensaries, that 79.4 per cent. were justified in the use of the dispensaries because of low economic status, and the rest because they sought the services of specialists or the use of equipment and apparatus which could not be obtained anywhere except in a dispensary at a price which they could afford to pay.

The bulk of dispensary work today is done in departments devoted to the treatment of special conditions. Not more than 20 per cent. of treatment is given in the department of internal medicine; the remainder is divided among pediatrics, surgery and specialties. The vast majority of patients seek the advice of specialists in the dispensary because they cannot meet the fees prevailing in private practice.

In view of that condition, it may be stated that the dispensaries have ceased to be institutions for the destitute only, and have come to occupy a very prominent place in the treatment of disease among the wage-earners of the community.

III. DISPENSARY POLICY AND EXECUTIVE DIRECTION

There exists no standard method of dispensary organization, either from the administrative or medical point of view. The dispensary has too often been treated as a Cinderella in the hospital household—neither sufficient funds nor sufficient thought have been given to its organization and work.

The problems encountered in dispensary administration are probably more complex and difficult than are the problems arising in the management of a hospital, yet the majority of institutions lack a definite policy with regard to dispensary work, and the administrative supervision is in too many institutions purely perfunctory. Likewise, with the exception of independent dispensaries, there seldom is an executive officer of training and ability attached to the dispensary whose duty it is to give undivided attention to the study of its problems and the development of adequate administrative procedure.

There is a need in most of the institutions of a clearly defined policy and responsibility to be formulated by the board of trustees and to be supervised by a joint committee representing the board of trustees, as well as the medical board. Provision should also be made, at least in the large institutions, for a full-time executive, who will carry out the policies of the board of trustees and devote his undivided thought and attention to the administrative problems of the dispensary. Many of the existing administrative deficiencies would be obviated by the existence of well defined policies and by the fixing of responsibility for their enforcement on specially designated full-time executives.

IV. FEES

The prevailing charge for admission, drugs, dressings, apparatus and so on varies from institution to institution. No effort has been made to standardize charges. They are invariably very low, although in some institutions the registration fee is as high as one dollar. Municipal hospitals have thus far refrained from charging any fees in their outpatient departments, although payments are accepted in such hospitals for the maintenance of ward patients. During the last year the charges in many institutions have been slightly increased. The increase in charges leads at times to a falling off of the number of patients, who seek treatment in institutions where the charges are lower. There is an evident need of an equalization policy in the matter of charges for treatment, as well as for medicine, dressings, etc., and an attempt along these lines should be made jointly by all the institutions, including the municipal.

At least three considerations must be borne in mind when the problem of fixing dispensary charges is undertaken. First,

all the institutions are in need of additional income for the purpose of improving the services; second, the majority of the wage-earners are able to pay part of the cost for skilled medical service, and third, there exists a class of patients, chronic invalids and the unemployed, who will be deprived of treatment altogether if the admission fee is demanded in every case. The fees should likewise be low or remitted to patients in tuberculosis and other similar clinics to which the patients are required to come for sanitary supervision. It is therefore necessary to adopt a system of carefully graded fees with a maximum not to exceed 50 cents, and to make that system uniform in the dispensaries throughout the city. The wage-earners in a more or less steady employment could pay a fee of 50 cents per visit without hardship. Moreover, considering the fact that the majority of patients come to the dispensary to seek the advice of specialists, the suggested increased fees would not be considered prohibitory to most of them. They are at present compelled to resort to the practically free services of the dispensary because they cannot meet the customary charges of specialists. The adoption of a 50 cent maximum fee would materially increase the present dispensary income, and would aid toward making possible the necessary improvements in dispensary service. It would help the institutions to pay salaries to physicians and to employ larger clerical, nursing and social service staffs to carry on more adequately the manifold functions of the dispensary and to meet the responsibilities toward the patients and the community. Even small salaries of from \$300 to \$600 yearly are often sufficient to keep good young physicians interested in their positions, and to lessen the medical "turn over" in the clinics.

The institutions which are poorly equipped, and which would be unable to render a superior grade of service, would lose many of their patients who, on paying a higher fee, would be more discriminating, and in this way the inferior institutions would be gradually eliminated.

V. REDUCTION IN WAITING TIME

The two things that first need amelioration in clinic procedure are the reduction in the waiting time before admission and the method of assignment of patients to clinics. In many instances, patients are made to wait unduly long periods of time, which is a hardship for most of them if they are employed, or, as in the case of mothers, if they have domestic duties. It is believed that this could be obviated to a large extent by the system of appointments, as is customary in private practice. That such a system can be made practical has been demonstrated by the American Red Cross Clinic for Children at LaHavre, and at the Mayo Clinic at Rochester, Minn.⁶

Because the dispensary plant is in many instances used only for several hours during the day, there is a great overcrowding of patients at most of the institutions. More extended use of the dispensary facilities would obviate the existing overcrowding in many instances and would allow for better individual attention than is at present accorded the average patient. When the extension of the use of the plant is impracticable, the principle of limitation of numbers should be applied, that is, no more patients should be admitted to the dispensary than the facilities of the institution in personnel and equipment would warrant.

The present practice of the lay registrars assigning patients to the several departments of the dispensary results in numerous transfers from one clinic to another, with the concomitant loss of time, and also in the condition that many clinics treat cases which do not belong to them.

6. The Red Cross plan is described by Dr. Edwards A. Park: *Mod. Hosp.* 13:101 (Aug.) 1919.

VI. THE DIAGNOSTIC CLINIC

To remedy this, it is suggested that each dispensary should have a diagnostic division, and patients with systemic diseases or suffering from conditions not easily ascertainable should receive the benefit of an examination by a group of physicians representing the several departments of the dispensary, and be assigned to the treatment departments after a preliminary examination has been made. Conditions in which the diagnosis is obvious, such as simple wounds or fractures, or when the disease or complaint is trivial and transient, such as a common "cold," could be disposed of without assignment to the diagnostic clinic.

Patients in need of a general examination should be assigned to the diagnostic division and subsequently sent for treatment to other departments. The physicians in the several departments would serve in the diagnostic division on a rotation basis. In this way the patients would receive the benefit that accrues from medical team work, and the physicians would have a much better opportunity for a complete study of patients than they do under the present form of organization. Consultants of broad experience and of recognized ability should be associated with and should actively participate in the work of both the diagnostic and the therapeutic departments.

VII. EDUCATIONAL OPPORTUNITIES

The waiting period of the patients has not been utilized in any of our dispensaries for educational purposes. Even if a system of appointments is introduced, it will not entirely obviate waiting. This period could be well utilized if moving pictures, dealing with certain health aspects, could be shown, large posters placed in the dispensary rooms, so that they could be read from the distance, or other methods of health education employed. Dietetic demonstrations would be of great value in this connection. The dispensary might also be used outside clinic hours for lectures, classes in dietetics, corrective gymnastics, teaching of hygiene, and similar activities; in other words, the dispensary should strive to become the educational center of the neighborhood.

VIII. ROOM ARRANGEMENT

It is important that in many of the institutions better arrangement of the facilities should be made so that the clinic rooms would be well lighted and ventilated and that the laboratories would be housed in readily accessible locations, and that clinics closely related in function should be in juxtaposition. The arrangement of the waiting rooms in large clinics could also be improved, and when feasible the exit from the building should be separated from the entrance. The social service department should likewise be made easily accessible and located in immediate proximity to the diagnostic department, which would facilitate the joint work of the two departments.

IX. EQUIPMENT

In order to make the services in dispensaries as attractive as possible for physicians, and in order that the patients may derive the greatest benefit from medical skill, it is imperative that the dispensaries be equipped with all the modern facilities for diagnosis and treatment of disease. Many institutions have meager laboratory and roentgen-ray facilities. The hospital laboratories on which many of the outpatient departments have to depend are too overcrowded with work for hospital patients to assume all the burden that proper medical work in the dispensaries would impose on them. In addition to the lack of adequate laboratory equipment, the dispensaries are seldom equipped with therapeutic workshops and with the facilities for hydrotherapy, mechanotherapy, thermotherapy and electrotherapy.

X. REMUNERATION OF DISPENSARY PHYSICIANS

Even if all the necessary physical facilities were provided in the dispensary, it would not attract physicians for continued and sustained application if there were no other benefits derived from dispensary practice. Medical ethics restrains physicians from deflecting patients from the dispensary to their private offices, and particularly with the present high cost of living it is very difficult for many to devote a great deal of time to dispensary practice, which, with a few exceptions, is not compensated. Remuneration, even though nominal, affords a stimulus to more conscientious performance of work, and makes possible a better discipline in the institutions. But what is even more important for the efficiency of the service is a medical organization correlating the dispensary service with that of the hospital, such as is already in vogue in the best institutions and should be adopted by others. The essential features of a correlated dispensary and hospital service are herewith suggested.

XI. CORRELATION OF DISPENSARY AND HOSPITAL SERVICE

The medical organization of outpatient departments which are connected with hospitals should be divided into two main branches corresponding to those of the hospital, namely, the medical and the surgical. The medical division of the hospital and that of the dispensary should be under one director. Likewise, the two surgical departments should have common direction. The specialties in each branch should be differentiated in accordance with the best interests of the medical and administrative organization of each institution. The outpatient service should be graded. The appointment to the lowest grade in the outpatient department should be made on a probationary basis of three or six months, and after a successful trial the probationer should, on the recommendation of the chief of clinic and with the approval of the board of trustees, be appointed a member of the dispensary staff in the lowest grade. On completion of a period of satisfactory service he should be promoted to a higher grade, and whenever the conditions warrant, should be made a member of the lowest grade of the visiting staff of the hospital. A rotating service for the junior members of the visiting staff of the hospital, allowing a combined service in the dispensary and in the hospital, is beneficial to hospital and dispensary alike.

Whenever such an arrangement exists, it affords physicians a stimulus to enter dispensary service; it adds to the experience of physicians, many of whom, on account of the limited facilities of hospitals, do not get the benefit of hospital association except during the one or two years of internship, and it gives to the hospitals a broader opportunity of choice of the visiting staff. A universal adoption of such a plan would be welcomed by the profession, and it would obviate to some degree, perhaps, the necessity for paying salaries to dispensary physicians. The opportunity for promotion to hospital rank counts for more than a salary reward for a routine day-to-day drudgery without hope for promotion. Such a plan would also dovetail with a medical school organization.

In detached or independent dispensaries, where such a plan of organization could not be effected, arrangements with medical schools for organizing graduate instruction could perhaps be made in order that the whole field of clinic work of this city should be permeated with the spirit of research and teaching, and in order that all existing facilities should be put to the most useful purpose.

The study of medical records has revealed the fact that the special institutions devoted to the treatment of particular conditions are almost invariably superior in their work to the corresponding branches of the general dispensaries. It seems important, therefore, that in making plans for the development of New York as a great medical teaching and research

center the facilities and clinical material of the special institutions should be correlated and utilized to the fullest extent.

XII. MEDICAL RECORDS

Adequate medical records prepared in a certain standard way and legibly written are one of the prime essentials of conscientious performance of work and of a scientific utilization of the clinic material. Under existing conditions, in which the physicians in the majority of instances are required to write histories in the rush of clinic work, and where there is no supervision over the keeping of histories, and no scientific or administrative stimulus for keeping them, the medical histories in many instances are little more than worthless. Often the essential findings of the physical examination and the ancillary laboratory tests, or the character and method of treatment, are not recorded.

The analysis of the thousands of medical records obtained from a large number of institutions, although inadequate as an exact portrayal of medical work, indicates, however, that in many instances dispensary work is of a slipshod character.

General physical examinations were found to be recorded in less than one fifth of all the cases examined. For certain conditions, such a procedure is probably unnecessary. In many others, however, the failure to make an adequate general physical examination is a serious omission and indicates to what extent the dispensaries could be improved if their responsibilities as agencies for the prevention of incipient disease and the discovery of remedial defects were fully realized. Then, again, the fact that the number of diagnoses recorded on the medical histories exceeds the number of physical or local examinations and the number of laboratory tests would indicate that the diagnoses are often forced without sufficient warrant. Even in such cases diagnosed as nephritis, for instance, records indicate that urinalysis was made in only 66.7 per cent. of instances. Among the cases of syphilis studied, in only 50 per cent. was an indication found that the patient had been given proper treatment.

For the efficient functioning of the clinics, it is desirable that clinic staff conferences should be held regularly and cases reviewed. The members of the staff should be urged to study intensively certain series of records and make analyses of them for presentation, discussion and publication.

With an administrative organization, as outlined in this series of recommendations, the keeping of adequate histories is quite feasible. In order that the histories may be made readily available for all purposes for which they may serve and in order that they may be kept in a uniform way, it is essential for a dispensary to maintain a central cross index filing system, such as has been successfully maintained at the Presbyterian Hospital of New York or at the Massachusetts General Hospital or at the Mayo Clinic, for example. The daily routine procedure in dispensaries should provide that at the close of each clinic session the clinic secretary should turn in the day's records to the filing clerk, who, on examination, files them in accordance with an established system, if the records contain all the information called for by the standard adopted. If the records are incomplete they should be returned to the physician for the supplementary information before they are placed on file. Before the clinic session begins, the records pertaining to patients who are expected to return on that particular day would be obtained by the clinic secretary from the filing clerk. Additional items indicating the patient's progress would be added, and the records again returned to the central file.

Although theoretically the central file is highly to be recommended for its manifold advantages, it has certain practical drawbacks. First of all, it is expensive, as it requires a considerable staff of trained and experienced file clerks with a

thorough understanding of medical terms. Its proper functioning is also dependent on the existence of clinic secretaries who would cooperate with the filing department in seeing that all the details are entered and that the department is notified daily in time to prepare histories for each clinic session.

Furthermore, the frequency of error in misfiling a record increases with the number of records handled, and accordingly the chances of a temporary loss of record are greater in the central files than they are in the individual files. Likewise, the question of available space for a central file must be considered before its adoption. A central file usually occupies a considerable amount of contiguous room space, while the decentralized file is easily distributed among the several clinic rooms.

Finally, the adaptability of a central file to the requirements of certain clinics, such as tuberculosis and venereal disease, which are called on to make periodic summaries of their work, must also be considered.

XIII. CLINIC SECRETARIES

Another important factor in increasing the efficiency of the clinic is the dispatch with which patients are prepared for examination. There are few institutions in this city at which clinic secretaries, as they are called, are employed. Wherever the experiment has been tried, whether with paid or volunteer workers, it has proved to be of great value. It is very important that clinic secretaries be generally employed as adjuncts in the discharge of clinical procedure. Many volunteers could be secured for the service from among those in the schools for social service, for whom such an experience would be of invaluable assistance in their future careers. A certain number of paid secretaries will, under any conditions be necessary in the clinic in order to train volunteers and facilitate the work of the physicians, and to spare the patients a great deal of waste of time and effort and also their occasional disappointment and discouragement.

XIV. FOLLOW-UP SERVICE

One of the tests of a dispensary's efficiency is the hold it exercises over its patients, for unless patients return for treatment until discharged, a great deal of the effort and money expended has been lost. As matters stand, the return visits, in some of the departments of the clinics are very few. In certain departments, like tuberculosis, venereal disease and children's, efforts are being made to bring the patient back through the follow-up system, which in the majority of institutions consists in notifying patients who fail to come on an appointed day that they should return to the clinic. Only in certain institutions are the patients visited by the agents of the dispensary and urged to come back. There are many reasons for the failure of the patients to return. They sometimes get discouraged; frequently, again, the symptoms which in the first instance drove them to the dispensary disappear, and it is not evident to them that they should continue treatment. In this study it has been shown that the majority of the patients gave "pain" as the chief symptom which prompted them to seek medical advice. It is essential for an efficient clinic to have an adequate number of workers who would be able to impress the patients with the importance of continuing treatment, even when the distressing or annoying symptoms disappear.

The number of persons with syphilis or gonorrhea who remain under treatment until discharged by the clinic is almost negligible, and no systematic efforts have been attempted to examine the families of the infected patients. In this respect the experience of tuberculosis clinics, where efforts in that direction have become a part of the routine of procedure, may be pointed out as a possibility for larger prophylactic opportunities of the venereal disease clinics. It is imperative

that the venereal disease clinics have at their command larger physical facilities, as well as more clerical, nursing and social service assistance, in order that they may take a proper part in the campaign for the eradication of venereal disease.

XV. THE NURSING ORGANIZATION

The nursing personnel of dispensaries is generally inadequate. The nurses are chiefly found in the children's, gynecologic, surgical and tuberculosis departments. Other departments are handicapped by lack of nursing assistance. Moreover, the nurses are frequently called on to do other than purely nursing duties, and their assignment to the dispensary is often contingent on the needs of the hospital. The practice established in certain institutions in which a part of the course in the training school for nurses is devoted to dispensary work, should be generally adopted and arrangements made in such a way that each of the pupil nurses should have several months' experience in the dispensary, which would be of great value to her. The pupil nurses should remain under the direction of a head nurse designated from the training school for the direction and instruction of the pupils. If such an arrangement could be effected in all the outpatient departments connected with hospitals maintaining a training school, the nursing service in dispensaries could be made much more adequate and economical than it is now, as the number of graduate nurses should be reduced to a minimum of one in some of the dispensaries.

XVI. THE SOCIAL SERVICE DEPARTMENT

The social service department could best do its work if it were in close cooperation with the admitting and diagnostic departments of the institution. The patient's first contact should be either with the social service department, where on rapid questioning, certain facts required by law would be ascertained about his social history, before he proceeds to the diagnostic or other departments of the institution; or this function could be performed by a proper registrar who, when directing the patient to the diagnostic clinic, attaches to his history sheet a slip to be returned by the physician with a check mark indicating whether or not the services of the social service department are required in the case. Such a routine procedure would automatically call the physician's attention to the availability of social service. Likewise a method should be worked out whereby reports on cases that are referred by physicians would automatically be sent to them as soon as available.

Because of the underutilization of the dispensaries by certain racial groups in our population, as a result of their ill adaptation to the new environment, it is important that the social service department learn to meet the racial point of view of the patients, as well as to have some one who would obtain, when necessary, the desired information in the language of at least the major foreign group using the dispensary.

The social service workers are often called on to perform functions which are not within the range of activities which should properly belong to them. Because in New York the hospital social workers are almost invariably nurses, they are in some instances devoting a great deal of time to nursing work. This is particularly true of the pediatric and tuberculosis clinics. Likewise, while visiting patients in their homes, the social service workers undertake at times what is tantamount to public health nursing. Social service workers need not be nurses; and whenever patients require public health nursing, arrangements for it should be made by the social service department with the Visiting Nurses' Association or the department of health, just in the same manner as other agencies are called on when the nature and exigencies of a case call for a special service.

There is a need of a standard or uniform social service nomenclature to designate certain conditions or procedures. The terms used at the present time are often vague and do not convey the same meaning to all who consult or use the records. The records of the social service department should be uniform and contain a certain amount of indispensable information. Digests of them should be filed with the medical records. The original full records might then be kept in the social service department.

The social service department has become recognized as an important part of the dispensary and hospital organization, and should be administratively incorporated as an integral part of the institution. It should be responsible before the board of trustees just as the other departments are, and all funds that are collected for its maintenance, if there be any special need for soliciting funds for any special department of an institution, should be placed in the treasury of the institution and paid out to the workers in the same way as salaries in other departments. There is an advantage, however, in having advisory committees of interested persons to discuss cases and to bring all the outside points of view and facilities available to assist in the work. On such committees, however, there should be representatives of the boards of trustees, the administrative heads, such as the superintendent, the heads of the training school for nurses, and also a representation from the several departments of the medical organization.

The work of medical social service has as yet not reached a plane where it can be said to be standardized in its aims and methods. It is still in a formative state. There is need for a concentration of effort on the part of all those interested to secure a crystallization of function and procedure.

A central clearing house for social work might be attempted in order to standardize procedure, to make comparative studies of the work in the several institutions of the city, and to minimize the waste of money and effort by dividing the city into sections, so that workers from one institution would not need to visit patients in distant parts of the city, but could "clear" through such a central office. Such an arrangement should be rendered more feasible if standard methods and standard record forms were used.

The suggested central clearing office, with its accumulated wealth of material and experience, would also be in a position to formulate plans for instruction to be given to those who desire to enter the field of social service.

XVII. DISTRICTING THE CITY FOR CLINIC PURPOSES

In order that the dispensaries may become what it is possible for them to be, namely, important medical, public health and social centers in the community, in addition to a reform of the present point of view and of the present organization, there is a need of a better public appreciation of the scope and function of the dispensary and of a regional division of the city with regard to dispensary service.

The first could be accomplished through proper publicity on the part of the dispensaries, and by reports more informing than those published by most of the institutions. In reports the work could be presented and analyzed in an interesting and instructive way, and the costs per patient or per attendance figured in accordance with an accurate and uniformly applied system.

The districting of the city for dispensary purposes may be difficult, because of the uneven distribution of the institutions and because of the needs of teaching clinics which do not desire to be restricted. In addition, there are a number of special institutions which cannot easily be included in any plan for the division of territory; likewise, denominational institutions might find it difficult to join in a district arrangement.

The advantages which would, however, accrue from a regional distribution of responsibility make it desirable to try such an arrangement. At first, perhaps, certain departments could organize their work on a district basis, following the successful example of cooperation on the part of the tuberculosis clinics. The pediatric, venereal disease, obstetric, social service and preventive medicine departments might find it most advantageous to adopt the district division of the field. Other departments might follow later, if these experiments should prove satisfactory.

The successful experience of the Association of Tuberculosis Clinics in raising the standard of equipment and procedure is worth while considering, particularly in connection with the venereal disease clinics, in which the variations in standards and records are so great at present as to render comparisons of their work of limited value. With a pooling of interests, and a uniform system of reporting and of scoring, great improvement could be expected.

Of all the departments of general dispensaries, the tuberculosis clinics, although far from ideal, are undoubtedly the most efficient. It is true that they differ from other branches of the dispensary in that their primary function is education, supervision and the securing of a change in environment, while in most of the other departments, the primary object is treatment; but similar cooperative arrangements could be established in other branches.

The Associated Out-Patient Clinics of the City of New York is the logical body to take the initiative in such a plan and to provide leadership to bring about needed reform in the dispensary practice and organization of this city.
